Estimation of Integrated Quadratic Covariation With Endogenous Sampling Times [*]

Yoann Potiron[†]and Per A. Mykland[‡]

Forthcoming in *Journal of Econometrics*

Abstract

When estimating high-frequency covariance (quadratic covariation) of two arbitrary assets observed asynchronously, simple assumptions, such as independence, are usually imposed on the relationship between the prices process and the observation times. In this paper, we introduce a general endogenous two-dimensional nonparametric model. Because an observation is generated whenever an auxiliary process called *observation time process* hits one of the two boundary processes, it is called the *hitting boundary process with time process* (HBT) model. We establish a central limit theorem for the Hayashi-Yoshida (HY) estimator under HBT in the case where the price process and the observation price process follow a continuous Itô process. We obtain an asymptotic bias. We provide an estimator of the latter as well as a bias-corrected HY estimator of the high-frequency covariance. In addition, we give a consistent estimator of the associated standard error.

1 Introduction

Covariation between two assets is a crucial quantity in finance. Fundamental examples include optimal asset allocation and risk management. In the past few years, using the increasing amount of high-frequency data available, many papers have been published about estimating this covariance. Suppose that the latent log-price of two arbitrary assets $X_t = (X_t^{(1)}, X_t^{(2)})$ follows a continuous Itô process

$$\begin{aligned} dX_t^{(1)} &:= \mu_t^{(1)} dt + \sigma_t^{(1)} dW_t^{(1)}, \quad (1) \\ dX_t^{(2)} &:= \mu_t^{(2)} dt + \sigma_t^{(2)} dW_t^{(2)}, \quad (2) \end{aligned}$$

where $\mu_t^{(1)}, \mu_t^{(2)}, \sigma_t^{(1)}, \sigma_t^{(2)}$ are random processes, and $W_t^{(1)}$ and $W_t^{(2)}$ are standard Brownian motions, with (random) high-frequency correlation $d\langle W^{(1)}, W^{(2)}\rangle_t = \rho_t dt$. Econometrics usually seeks to infer the *integrated covariation*

$$\langle X^{(1)}, X^{(2)}\rangle_t = \int_0^t \rho_u \sigma_u^{(1)} \sigma_u^{(2)} du.$$

Earlier results were focused on estimating the integrated variance of a single asset, starting from the probabilistic point of view (Genon-Catalot and Jacod (1993), Jacod (1994)). Barndorff-Nielsen and Shephard (2001, 2002) introduced the problem in econometrics. Adapted to two dimensions, if each process is observed simultaneously at (possibly random) times $\tau_{0,n} := 0$, $\tau_{1,n}$, . . . , $\tau_{N_n,n}$ the *realized covariation* $\left[X^{(1)}, X^{(2)}\right]_t$ is defined as the sum of cross log returns

$$\left[X^{(1)}, X^{(2)}\right]_t = \sum_{\tau_{i,n} \leq t} \Delta X_{\tau_{i,n}}^{(1)} \Delta X_{\tau_{i,n}}^{(2)}, \quad (3)$$

where for any positive integer i, $\Delta X_{\tau_{i,n}}^{(k)} = X_{\tau_{i,n}}^{(k)} - X_{\tau_{i-1,n}}^{(k)}$ corresponds to the increment of the kth process between the last two sampling times. As the observation intervals $\Delta\tau_{i,n}$ get closer (and the number of observations N_n goes to infinity), $\left[X^{(1)}, X^{(2)}\right]_t \xrightarrow{\mathbb{P}}$

$\langle X^{(1)}, X^{(2)} \rangle_t$ (see e.g. Theorem I.4.47 in Jacod and Shiryaev (2003)). Furthermore, when the observation times $\tau_{i,n}$ are independent of the prices process X_t, its estimation error follows a mixed normal distribution (Jacod and Protter (1998), Zhang (2001), Mykland and Zhang (2006)). This gives us insight on how to estimate the integrated covariation. However, in practice, these two assumptions are usually not satisfied. The observation times of the two assets are rarely *synchronous* and there is *endogeneity* in the price sampling times.

The first issue has been studied for a long time. The lack of synchronicity often creates undesirable effects in inference. If we sample at very high frequencies, we observe the Epps effect (Epps (1979)), i.e. the correlation estimates are drastically decreased compared to an estimate with sparse observations. Hayashi and Yoshida (2005) introduced the so-called *Hayashi-Yoshida estimator* (HY)

$$\langle \widehat{X^{(1)}, X^{(2)}} \rangle_t^{HY} = \sum_{\tau^{(1)}_{i,n}, \tau^{(2)}_{j,n} < t} \Delta X^{(1)}_{\tau^{(1)}_{i,n}} \Delta X^{(2)}_{\tau^{(2)}_{j,n}} \mathbf{1}_{\left\{ [\tau^{(1)}_{i-1,n}, \tau^{(1)}_{i,n}) \cap [\tau^{(2)}_{j-1,n}, \tau^{(2)}_{j,n}) \neq \emptyset \right\}}, \tag{4}$$

where $\tau^{(k)}_{i,n}$ are the observation times of the kth asset. Note that if the observations of both processes occur simultaneously, (3) and (4) are equal. The consistency of this estimator was achieved in Hayashi and Yoshida (2005) and Hayashi and Kusuoka (2008). The corresponding central limit theorems were investigated in Hayashi and Yoshida (2008, 2011) under strong predictability of observation times, which is a more restrictive assumption than only assuming they are stopping times but still allows some dependence between prices and observation times. Recently, Koike (2014, 2015) extended the pre-averaged Hayashi-Yoshida estimator first under predictability of observation times, and then under a more general endogenous setting of stopping times. Other examples of high-frequency covariance estimators can be found in Zhang (2011), Barndorff-Nielsen et al. (2011), Aït-Sahalia et al. (2010), Christensen et al. (2010, 2013).

In a general one-dimensional endogenous model, the asymptotic behaviour of the realized volatility (3) has been investigated in the case of sampling times given by hitting times on a grid (Fukasawa (2010a), Robert and Rosenbaum (2011, 2012), Fukasawa and Rosenbaum (2012)). Due to the regularity of those three models (see the discussion in the latter paper), they don't obtain any bias in the limit distribution of the normalized error. Also, the case of strongly predictable stopping times is treated in Hayashi et al. (2011). Finally, two general results (Fukasawa (2010b), Li and al. (2014)) showed that we can identify and estimate the asymptotic bias.

The primary goal of this paper is to bias-correct the HY. Note that estimating the bias is more challenging than in the volatility case because observations are asynchronous. In particular, the estimator will involve a quantity that can be considered as the *tricity* of Li et al. (2014), but with a more intricate definition because of the asynchronicity in sampling times. This new definition can be seen as an analogy with the generalization of the RV estimator (3) by the HY estimator (4).

Another very important issue to address is the estimation of the asymptotic standard deviation. First, because the model is more general than in the no-endogeneity work, the theoretical asymptotic variance will be different. Consequently, a new variance estimator, which takes into proper account the endogeneity, will be given.

The authors want to take no position on the joint distribution of the log-return and the next observation time that corresponds to an asset price change because they know that their unknown relationship is most likely contributing to the bias and the variance of the high-frequency covariance's estimate when we (wrongly) assume full independence between the price process and observation times. For this purpose, they introduce the *hitting boundary process with time process* (HBT) model.

Finally, techniques developed in the proofs are innovative in the sense that they reduce the normalized error of the Hayashi-Yoshida estimator to a discrete process, which is locally a uniformly ergodic homogeneous Markov chain. Thus, the problem can be solved locally, and because we assume that the volatility of assets is continuous, the error of approximation between the local Markov structure and the real structure of the normalized error vanishes asymptotically. This technique is not problem-specific, and it can very much be applied to other estimators dealing with temporal data.

The paper is organized as follows. We introduce the HBT model in Section 2. Examples covered by this model are given in Section 3. The main theorem of this work, the limit distribution of the normalized error is given in Section 4. Estimators of the asymptotic bias and variance are provided in Section 5. We carry out numerical simulations in Section 6 to corroborate the theory. Proofs are developed in Appendix.

2 Definition of the HBT model

We first introduce the model in 1-dimension. We assume that for any positive integer i, τ_{i+1} is the next arrival time (after τ_i) that corresponds to an actual change of price. In particular, several trades can occur at the same price Z_{τ_i} between τ_i and τ_{i+1}, but no trade can occur with a price different than Z_{τ_i} before τ_{i+1}. We also assume that X_t is the efficient (log) price of the security of interest. In addition, we assume that the observations are noisy and that we observe $Z_{\tau_i} := X_{\tau_i} + \epsilon_{\tau_i}$ where the microstructure noise ϵ_{τ_i} can be expressed as a known function of the observed prices $Z_0, \ldots, Z_{\tau_i}$. As an example, Robert and Rosenbaum (2012) showed in (2.3) in p. 5 that the model with uncertainty zones can be written with that noise structure if we assume that we know the friction parameter η. Finally, we define $\alpha > 0$ as the tick size, and we assume that the observed price Z_{τ_i} lays on the tick grid, i.e. there exists positive integers m_i such that $Z_{\tau_i} := m_i \alpha$.

Empirically, no economical model based on rational behaviors of agents on the stock markets, that shed light on the relationship between the efficient return ΔX_{τ_i} and time before the next price change $\Delta \tau_i = \tau_i - \tau_{i-1}$, has won unanimous support. When arrival times are independent of the asset price, it follows directly from the continuous Itô-assumption that the dependence structure is such that the return ΔX_{τ_i} is a function of $\Delta \tau_i$. The longer we wait, the bigger the variance of the return is expected to be. In this paper, we take the opposite point of view by building a model in which τ_i is defined as a function of the efficient price path. For that purpose, we define the *observation time process* $X_t^{(t)}$ that will drive the observation times. We also define the *down process* $d_t(s)$ and the *up process* $u_t(s)$. Note that for any $t \geq 0$, we assume that d_t and u_t are functions on $\mathbb{R}^+$. We also assume that the down process takes only negative values and that the up process takes only positive values. A new observation time will be generated whenever one of those two processes is hit by the increment of the observation time process. Then, the increment of the observation time process will start again from 0, and the next observation time will be generated whenever it hits the up or the down process. Figure 1 illustrates the HBT model. Formally, we define $\tau_0 := 0$ and for any positive integer i as

$$\tau_i := \inf \left\{ t > \tau_{i-1} : \Delta X^{(t)}_{[\tau_{i-1},t]} \notin \left[d_t \left(t - \tau_{i-1} \right), u_t \left(t - \tau_{i-1} \right) \right] \right\}, \tag{5}$$

where $\Delta Y_{[a,b]} := Y_b - Y_a$. Note that if the observation time process $X^{(t)}_t$ is equal to the price process X_t itself, then the price will go up (respectively go down) whenever it hits the up process (down process). Note also that if the time process, the up process and the down process are independent of the efficient price process, then the arrival times are independent of the efficient price process. We assume that the two-dimensional process $(X_t, X^{(t)}_t)$ is an Itô-process. Section 3.1 provides examples of the literature identifying the observation time process, the down process and the up process.

Generalizing to two dimensions is straightforward. We define $X^{(t,k)}_t$ for $k = 1, 2$ to be the observation time process associated with the kth price process , $u^{(k)}_t$ the up process, $d^{(k)}_t$ the down process, and the arrival times $\tau^{(k)}_i$ generated by (5). We also define the four dimensional process $Y_t := (X^{(1)}_t, X^{(2)}_t, X^{(t,1)}_t, X^{(t,2)}_t)$, and assume Y_t follows an Itô-process with volatility

$$\sigma_t := \begin{pmatrix} \sigma^{1,1}_t & \sigma^{1,2}_t & \sigma^{1,3}_t & \sigma^{1,4}_t \\ \sigma^{2,1}_t & \sigma^{2,2}_t & \sigma^{2,3}_t & \sigma^{2,4}_t \\ \sigma^{3,1}_t & \sigma^{3,2}_t & \sigma^{3,3}_t & \sigma^{3,4}_t \\ \sigma^{4,1}_t & \sigma^{4,2}_t & \sigma^{4,3}_t & \sigma^{4,4}_t \end{pmatrix}.$$

In particular, we have $dY_t = \mu_t dt + \sigma_t dW_t$, where W_t is a four dimensional standard Brownian motion (for $i = 1, \ldots, 4$ and $j = 1, \ldots, 4$ such that $i \neq j$, $W^{(i)}_t$ is independent of $W^{(j)}_t$). If we set $\zeta_t = \sigma_t \sigma^T_t$, then the integrated covariance (or quadratic covariation) process is given by $\langle Y, Y \rangle_t = \int_0^t \zeta_s ds$. Let ρ_t be the associated correlation process of Y_t, i.e. for $i = 1, \ldots, 4$ and $j = 1, \ldots, 4$ we set $\rho^{i,j}_t = \zeta^{i,j}_t (\zeta^{i,i}_t)^{-1}$. Finally, it is useful sometimes to see Y_t as a four dimensional vector expressed as in equations (1) and (2). For $k = 1, \ldots, 4$ we define the volatility of the kth process as $\sigma^{(k)}_t := (\zeta^{k,k}_t)^{\frac{1}{2}}$, we can thus express $Y^{(k)}_t$ as

$$dY^{(k)}_t = \mu^{(k)}_t dt + \sigma^{(k)}_t dB^{(k)}_t$$

where $B^{(k)}_t$ is a standard Brownian motion, which typically depends on $B^{(l)}_t$ for $l = 1, \ldots, 4$.

3 Examples

We insist on the fact that estimators of covariance and associated asymptotic variance given in this paper don't require any knowledge of the structure of the observation time process, the up process and the down process. Nonetheless, for financial and economic interpretation purposes, the reader might be interested in getting an idea on how those processes behave in practice. We provide in this section several examples from the literature as well as possible extensions of the model with uncertainty zones of Robert and Rosenbaum (2011) that can be expressed as HBT models.

3.1 Endogenous models contained in the HBT class

Example 1. (hitting constant boundaries) The simplest endogenous semi-parametric model we can think of is a model where the time process $X_t^{(t)}$ is equal to the price process X_t, and times are generated by hitting a constant barrier. Formally, it means that there exists a two-dimensional parameter (θ_u, θ_d) such that the up process is equal to θ_u and the down process is equal to θ_d. We don't assume noise in that model.

Example 2. (hitting constant boundaries of the tick size) One issue with Example 1 is that the efficient price X_{τ_i}, which is observed because no microstructure noise is assumed in the model, is not necessarily a modulo of the tick size α if θ_u and θ_d are not multiples of α. To make Example 3.1 feasible in practice, we assume here that the constant barriers θ_u and θ_d are respectively equal to the tick size α and its additive inverse $-\alpha$. We also assume that $Z_{\tau_i} := X_{\tau_i}$.

Example 3. (hitting constant boundaries of the jump size) The issue with Example 2 is that the absolute jump size of the observed price Z_{τ_i} is α. On the contrary, in practice the absolute jump size can actually be bigger than the tick size α. In the notation of Robert and Rosenbaum (2011), for any positive integer i, we introduce a discrete variables L_i which corresponds to the observed price jump's tick number between τ_i and τ_{i+1}, with $L_i \geq 1$. We assume that L_i is bounded. The arrival times are defined recursively as $\tau_0 := 0$ and for any positive integer i as

$$\tau_i := \inf\Big\{t > \tau_{i-1} : X_t = X_{\tau_{i-1}} - L_{i-1}\alpha \text{ or } X_t = X_{\tau_{i-1}} + L_{i-1}\alpha\Big\}.$$

We assume that L_i are IID and independent of the other quantities. We finally assume that $Z_{\tau_i} := X_{\tau_i}$. The up and down processes are piecewise constant in t and constant in s, defined for any $s \geq 0$ as

$$\begin{aligned} d_t(s) = &\quad -L_{i-1}\alpha \quad \text{for } t \in (\tau_{i-1}, \tau_i] \\ u_t(s) = &\quad L_{i-1}\alpha \quad \text{for } t \in (\tau_{i-1}, \tau_i] \end{aligned}$$

Example 4. (model with uncertainty zones) We go one step further than Example 3 and introduce now the model with uncertainty zones of Robert and Rosenbaum (2011). In a frictionless market, we can assume that a trade with change of price Z_{τ_i} will occur whenever the efficient price process crosses one of the mid-tick values $Z_{\tau_{i-1}} + \frac{\alpha}{2}$ or $Z_{\tau_{i-1}} - \frac{\alpha}{2}$. In that case, if the efficient price process hits the former value, we would observe an increment of the observed price $Z_{\tau_i} = Z_{\tau_{i-1}} + \alpha$ and if it hits the former value, we would observe a decrement $Z_{\tau_i} = Z_{\tau_{i-1}} - \alpha$. There are two reasons why in practice such a frictionless model is too simplistic. The first reason is that the absolute value of the increment (or the decrement) of the observed price can be bigger than the tick size α and was already pointed out in Example 3. We will thus keep the notation L_i in this example. The second reason is that the frictions induce that the transaction will not exactly occur when the efficient process is equal to the mid-tick values. For this purpose in the notation of Robert and Rosenbaum (2012), let $0 < \eta < 1$ be a parameter that quantifies the aversion to price changes of the market participants. If we let $X_t^{(\alpha)}$ be the value of X_t rounded to the nearest multiple of α, the sampling times are defined recursively as $\tau_0 := 0$ and for any positive integer i as

$$\tau_i := \inf\Big\{t > \tau_{i-1} : X_t = X^{(\alpha)}_{\tau_{i-1}} - \alpha\big(L_{i-1} - \frac{1}{2} + \eta\big) \text{ or } X_t = X^{(\alpha)}_{\tau_{i-1}} + \alpha\big(L_{i-1} - \frac{1}{2} + \eta\big)\Big\}$$

The observed price is equal to the rounded efficient price $Z_{\tau_i} := X^{(\alpha)}_{\tau_i}$. The time process $X_t^{(t)}$ is again equal to the price process X_t itself in this model. The up and down processes are piecewise constant in t and constant in s, defined for any $s \geq 0$ as

$$\begin{aligned} d_t(s) = &\quad -L_{i-1}\alpha\mathbf{1}_{\{X_{\tau_{i-1}} < X_{\tau_{i-2}}\}} - (2\eta + L_{i-1} - 1)\,\alpha\mathbf{1}_{\{X_{\tau_{i-1}} > X_{\tau_{i-2}}\}} \quad \text{for } t \in (\tau_{i-1}, \tau_i] \\ u_t(s) = &\quad L_{i-1}\alpha\mathbf{1}_{\{X_{\tau_{i-1}} > X_{\tau_{i-2}}\}} + (2\eta + L_{i-1} - 1)\,\alpha\mathbf{1}_{\{X_{\tau_{i-1}} < X_{\tau_{i-2}}\}} \quad \text{for } t \in (\tau_{i-1}, \tau_i] \end{aligned}$$

where $\mathbf{1}_A$ is the indicator function of A. Note that in the case where $\eta = \frac{1}{2}$, we are back to Example 3.

Example 5. (times generated by hitting an irregular grid model) The fourth model we are looking at is called *times generated by hitting an irregular grid model.* We follow the notation of Fukasawa and Rosenbaum (2012) and consider the irregular grid $\mathcal{G} = \{p_k\}_{k \in \mathbb{Z}}$, with $p_k < p_{k+1}$. We set $\tau_0 = 0$ and for $i \geq 1$

$$\tau_i = \inf \Big\{ t > \tau_{i-1} : X_t \in \mathcal{G} - \{X_{\tau_{i-1}}\} \Big\},$$

where $\mathcal{G} - \{X_{\tau_{i-1}}\}$ is the set obtained by removing $\{X_{\tau_{i-1}}\}$ from $\mathcal{G}$. We can rewrite it as an element of the HBT model where the time process is equal to the price process, and for all $s \geq 0$ the up and down processes are defined as

$$\begin{aligned} d_t(s) = &\quad p_{k-1} - p_k \quad \text{ for } t \in (\tau_{i-1}, \tau_i] \\ u_t(s) = &\quad p_{k+1} - p_k \quad \text{ for } t \in (\tau_{i-1}, \tau_i], \end{aligned}$$

where k is the (random) index such that $p_k = X_{\tau_{i-1}}$.

Example 6. (structural autoregressive conditional duration model) There have been several drafts for this model. We follow here a former version (Renault et al. (2009)), because we can directly express it as an element of the HBT model[1]. In the structural autoregressive conditional duration model, the time τ_i when the next event occurs is given by $\tau_0 = 0$ and for $i > 0$

$$\tau_i = \inf \Big\{ t > \tau_{i-1} : A_t - A_{\tau_{i-1}} = \tilde{d}_{\tau_{i-1}} \text{ or } A_t - A_{\tau_{i-1}} = \tilde{c}_{\tau_{i-1}} \Big\} \tag{6}$$

where A_t is a standard Brownian motion (not necessarily independent of X_t). Expressed as an element of the HBT model, we have that the time process $X_t^{(t)}$ is equal to the Brownian motion A_t and for all $s \geq 0$

$$\begin{aligned} d_t(s) = &\quad \tilde{d}_{\tau_{i-1}} \text{ for } \quad t \in (\tau_{i-1}, \tau_i] \\ u_t(s) = &\quad \tilde{c}_{\tau_{i-1}} \text{ for } \quad t \in (\tau_{i-1}, \tau_i]. \end{aligned}$$

---

[1] Generating the sampling times (5) of the HBT model as a first hitting-time of a unique barrier instead of the first hitting time of one of two barriers as in the latter version of Renault et al. (2014) wouldn't change much the proofs of this paper, but we chose the two-boundaries setting because it seems more natural if interpretation of time processes, up processes and down processes is needed.

3.2 Possible extensions of the model with uncertainty zones

The model with uncertainty zones of Robert and Rosenbaum (2011) introduced in Example 4, which is semi-parametric, assumes that the observed price is the efficient price rounded to the nearest tick value $Z_{\tau_i} = X^{(\alpha)}_{\tau_i}$ and thus the noise is equal to $\epsilon_i := \alpha(\frac{1}{2}-\eta)$ if the last trade increased the price and $\epsilon_i := -\alpha(\frac{1}{2}-\eta)$ if the last trade decreased the price. In particular, the noise is auto-correlated and correlated to the efficient price. Because of this specific noise distribution, it is directly possible to estimate the underlying friction parameter η without any data pre-processing such as preaveraging (see Robert and Rosenbaum (2012)). We believe the model with uncertainty zones is a very interesting starting point, because all the endogenous and noise structure of the model is reduced to the estimation of the 1-dimensional friction parameter η. Nevertheless, as this semi-parametric model wants to be the simplest, it suffers from several issues. We will investigate two of them in the following.

First, the model doesn't allow for asymmetric information between the buyers and the sellers. Define η^+ and η^-, which are respectively the aversion to a positive price change and a negative price change. As a positive price change means that a buyer decided to put an order at the best ask price and a negative price change corresponds to a seller that puts an order at the best bid price (if we assume that cancel and repost orders are not the reason why the price changed), the difference $\eta^+ - \eta^-$ can be seen as a measure of information asymmetry. We define $\tau_0 := 0$ and recursively for i any positive integer

$$\tau_i := \inf\Big\{t > \tau_{i-1} : X_t = X^{(\alpha)}_{\tau_{i-1}} - \alpha\big(L_i - \frac{1}{2} + \eta^-\big) \text{ or } X_t = X^{(\alpha)}_{\tau_{i-1}} + \alpha\big(L_i - \frac{1}{2} + \eta^+\big)\Big\}.$$

Note that the HBT class contains this model and that it can be directly fitted if we slightly modify $\hat{\eta}$ in Robert and Rosenbaum (2012) to estimate η^+ and η^-. One possible application would be to build a test of asymmetric information $\eta^+ := \eta^-$. This is beyond the scope of this paper.

One other issue is that the authors don't do any model checking in their work. According to their empirical work (see pp. 359-361 of Robert and Rosenbaum (2011)), the estimated values for η are stable accross days for the ten French assets tested. Stability of η favors their model but by doing so, the model doesn't allow any other structure than the full-endogeneity for the sampling times. Even if the true structure of sampling times is (mostly) independent of the asset price, we will still estimate an η that will be stable across days. If we allow the time process to be different from the price process itself, we can estimate the correlation $\rho^{1,3}$ between them and see how endogenous the sampling times are (the bigger $\left|\rho^{1,3}\right|$ is, the more endogenous the sampling times are). We would need to add more general microstructure noise in the model, and thus this is left for further work.

4 Main result

4.1 Assumptions and Theorem

Without loss of generality, we fix the horizon time $T := 1$, and we consider $[0,1]$ to represent the course of an economic event, such as a trading day. We first introduce the definition of stable convergence, which is a little bit stronger than usual convergence in distribution and needed for statistical purposes of inference, such as the prediction value of the high-frequency covariance and the construction of a confidence interval at a given confidence level.

Definition 1. We suppose that the random processes Y_t, μ_t and σ_t are adapted to a filtration $(\mathcal{F}_t)$. Let Z_n be a sequence of $\mathcal{F}_1$-measurable random variables. We say that Z_n converges stably in distribution to Z as $n \to \infty$ if Z is measurable with respect to an extension of $\mathcal{F}_1$ so that for all $A \in \mathcal{F}_1$ and for all bounded continuous[2] functions f, $\mathbb{E}\left[\mathbf{1}_A f\left(Z_n\right)\right] \to \mathbb{E}\left[\mathbf{1}_A f\left(Z\right)\right]$ as $n \to \infty$.

In the setting of Section 2, the target of inference, the integrated covariation, can be written for all $t \in [0,1]$ as

$$\langle X^{(1)}, X^{(2)}\rangle_t := \int_0^t \sigma_s^{(1)}\sigma_s^{(2)}\rho_s^{1,2}ds.$$

---

[2] Note that the continuity of f refers to continuity with respect to the Skorokhod topology of $\mathbb{D}[0,1]$. Nevertheless, we can also use continuity given by the sup-norm, because all our limits are in $\mathbb{C}[0,1]$. One can look at Chapter VI of Jacod and Shiryaev (2003) as a reference. For further definition of stable convergence, one can look at Rényi (1963), Aldous and Eagleson (1978), Chapter 3 (p. 56) of Hall and Heyde (1980), Rootzén (1980), and Section 2 (pp. 169-170) of Jacod and Protter (1998).

We are providing now the asymptotics. We want to make the number of observations go to infinity asymptotically. The idea is to scale and thus keep the structure that drives the next return and the next observation time, while making the tick size vanish (and thus the number of observations explode on $[0,1]$). Formally, we let the tick size $\alpha > 0$ and we define the observation times $\mathrm{T}_\alpha := \left\{\tau^{(k)}_{i,\alpha}\right\}^{k=1,2}_{i\geq 0}$ such that for $k = 1, 2$ we have $\tau^{(k)}_{0,\alpha} := 0$ and for i any positive integer

$$\tau^{(k)}_{i,\alpha} := \inf\left\{t > \tau^{(k)}_{i-1,\alpha} : \Delta X^{(t,k)}_t \notin \left[\alpha d^{(k)}_t(t-\tau^{(k)}_{i-1,\alpha}), \alpha u^{(k)}_t(t-\tau^{(k)}_{i-1,\alpha})\right]\right\}.$$

We define the HY estimator when the tick size is equal to α as

$$\langle \widehat{X^{(1)}, X^{(2)}} \rangle^{HY}_{t,\alpha} := \sum_{0<\tau^{(1)}_{i,\alpha}\ ,\ \tau^{(2)}_{j,\alpha}<t} \Delta X^{(1)}_{\tau^{(1)}_{i,\alpha}} \Delta X^{(2)}_{\tau^{(2)}_{j,\alpha}} \mathbf{1}_{\left\{[\tau^{(1)}_{i-1,\alpha},\tau^{(1)}_{i,\alpha})\cap[\tau^{(2)}_{j-1,\alpha},\tau^{(2)}_{j,\alpha})\neq\emptyset\right\}}. \tag{7}$$

We now give the assumptions needed to prove the central limit theorem of (7). We need to introduce some definitions for this purpose. In view of the different models introduced in Section 3, there are three different possible assumptions regarding the correlation between the time processes $X^{(t)}_t$ and the price processes X_t. The first possibility is that they can be equal for all $0 \leq t \leq T$. In this case we define $\lambda^{\min}_t$ as the smallest eigen-value of $(\sigma^{(i,j)}_t)^{j=1,2}_{i=1,2}$. The second scenario is that for one $k \in 1, 2$ we have $X^{(k)}_t := X^{(t,k)}_t$, but the other time process is different from its associated price process. In that case, we define $\lambda^{\min}_t$ the smallest eigen-value of $(\sigma^{(i,j)}_t)^{j\in\{1,2,3,4\}-\{k+2\}}_{i\in\{1,2,3,4\}-\{k+2\}}$. The third possible setting is that the time process is different from its associated asset price for both assets, and we let $\lambda^{\min}_t$ the smallest eigen-value of σ_t in that case. Assumption $(A1)$ provides conditions on the price processes $X^{(1)}_t$ and $X^{(2)}_t$, the time processes $X^{(t,1)}_t$ and $X^{(t,2)}_t$ as well as their covariance matrix σ_t. There are two types of assumptions in $(A1)$. First, we want to get rid of the drift in the proofs, and this will be done using condition $(A1)$ together with the Girsanov theorem and local arguments (see e.g. pp.158-161 in Mykland and Zhang (2012)). This is a very standard assumption in the literature of financial econometrics. Furthermore, we assume that the covariance matrix σ_t is continuous.

Assumption (A1). The drift μ_t, the volatility matrix σ_t and the (four dimensional) Brownian motion W_t are adapted to a filtration $(\mathcal{F}_t)$. Also, μ_t is integrable and locally bounded. Furthermore, σ_t is continuous. Finally, we assume that $\inf_{t\in(0,1]} \lambda^{\min}_t > 0$ a.s.

Remark 1. (robustness to jumps in volatility) The proof techniques, holding the volatility constant on small blocks, require the "continuity of volatility". This is the same strategy as in Mykland and Zhang (2009) and Mykland (2012) where the volatility process follows a continuous Itô process. Nonetheless, following the same line of reasoning as for the proof of Remark 6, we can add a finite number of jumps in the volatility matrix. The proof of Theorem 1 will break in the case of infinite number of jumps in σ_t.

The following condition roughly assumes that both time processes can't be equal to each other, even on a very small time interval. Specifically, we will assume that there is a constant strictly smaller than 1 such that the module of the *instantaneous high-frequency correlation* $\rho_t^{3,4}$ can't be bigger than this constant. In practice, assumption $(A2)$ is harmless.

Assumption (A2). For all $t \in [0,1]$ we have

$$\rho_t^{3,4} \in [\rho_-^{3,4}, \rho_+^{3,4}], \tag{8}$$

where $\max(\mid \rho_-^{3,4} \mid, \mid \rho_+^{3,4} \mid) < 1$.

The next assumption deals with the down process d_t and the up process u_t. It is clear that d_t and u_t have to be known with information at time t, which is why we assume that they are adapted to $(\mathcal{F}_t)$. The rest of assumption $(A3)$ is very technical and we only try to be as general as we can with respect to the proof techniques we will use. The reader should understand Assumption $(A3)$ as "assume the worst dependence structure possible between the return ΔX_{τ_i} and the time increment $\Delta\tau_i$, knowing that they follow the HBT model". We insist once again on the fact that we only make the dependence structure as bad as we can in our model so that we can investigate how biased the HY estimator can be in practice, and how much the estimates of the variance assuming no endogeneity are wrong.

Assumption (A3). For both assets $k = 1, 2$, define the couple of the down process and the up process $g_t^{(k)} := (d_t^{(k)}, u_t^{(k)})$ and let $g_t := (g_t^{(1)}, g_t^{(2)})$. We assume that

$$\begin{array}{rccl} g^{(k)}: & \mathbb{R}^+ & \to & (\mathbb{R}^+ \to \mathbb{R}^- \times \mathbb{R}^+) \\ & t & \mapsto & g_t^{(k)} \end{array}$$

is adapted to $(\mathcal{F}_t)$. Moreover, there exists two non-random constants $0 < g^- < g^+$ such that a.s. for any $t \in [0,1]$ and for any $s \geq 0$

$$g^- \leq \min(-d_t^{(k)}(s), u_t^{(k)}(s)) \leq \max(-d_t^{(k)}(s), u_t^{(k)}(s)) \leq g^+ \tag{9}$$

Furthermore, there exists non-random constants $K > 0$ and $d > 1/2$ such that a.s.

$$\forall s \geq K \ , \ g_t\left(s\right) = g_t\left(K\right), \tag{10}$$

$$\forall t \geq 0, \ g_t \text{ is differentiable and } \forall s \geq 0, \ \max\left(|(d_t^{(k)})'(s)|, |(u_t^{(k)})'(s)|\right) \leq K, \tag{11}$$

$$\forall \ (u,v) \in [0,1]^2 \text{ s.t. } 0 < u < v, \quad \|g_v - g_u\|_\infty \leq K|v-u|^d, \tag{12}$$

where $\|(f_1, f_2)\|_\infty = \sup\limits_{w \geq 0} \max\left(|f_1\left(w\right)|, |f_2\left(w\right)|\right)$.

Remark 2. Consider the space $\mathcal{C}$ of constants defined in Assumption $(A3)$

$$\mathcal{C} := \Big\{(g^-, g^+, K, d) \text{ s.t. } 0 < g^- < g^+ \ , \ K > 0 \ , \ d > \frac{1}{2}\Big\}.$$

For any $c \in \mathcal{C}$, we define $\mathcal{G}(c)$ to be the functional subspace of $\mathbb{R}^+ \to (\mathbb{R}^+ \to \mathbb{R}^- \times \mathbb{R}^+)^2$ such that $\forall g \in \mathcal{G}$, g satisfies (9), (10), (11) and (12). When there is no room for confusion, we use $\mathcal{G}$. Assumption (A3) is equivalent to

$$\exists c \in \mathcal{C} \text{ s.t. } \forall t \in [0,1] \ , \ g_t \in \mathcal{G}(c).$$

Remark 3. The advised reader will have noticed that Example 3, Example 4, Example 5 and Example 6, where time processes are piecewise-constant and may depend on n, don't follow Assumption $(A3)$. The adaptation of Theorem 1 proofs in those examples is discussed in Appendix 8.5. We have made the choice not to state more general conditions to keep tractability of Assumption $(A3)$.

The last assumption is only technical, and also appears in the literature (Mykland and Zhang (2012), Li et al. (2014)).

Assumption (A4). The filtration $(\mathcal{F}_t)$ is generated by finitely many Brownian motions.

We can now state the main theorem.

Theorem 1. *Assume* $(A1)-(A4)$*. Then, there exist processes* AB_t *and* AV_t *adapted to* $(\mathcal{F}_t)$ *such that stably in law as the tick size* $\alpha \to 0$*,*

$$\alpha^{-1}\left(\widehat{\langle X^{(1)}, X^{(2)}\rangle}^{HY}_{t,\alpha} - \langle X^{(1)}, X^{(2)}\rangle_t\right) \to AB_t + \int_0^t (AV_s)^{1/2}\, dZ_s, \tag{13}$$

where Z_t *is a Brownian motion independent of the underlying* σ*-field. The asymptotic bias* AB_t *and the asymptotic variance* AV_t *are defined in Section* 4.3 *and estimated in Section* 5*.*

Remark 4. (path-bias) Note that the asymptotic bias term AB_t on the right-hand side of (13) doesn't mean that the Hayashi-Yoshida estimator is *biased*, but rather *path-biased*. The latter is a weaker statement which means that once we have seen a path, there is a *bias* for the HY estimator on this specific path of value AB_t. In practice, we only get to see one path and thus *bias* and *path-bias* can be confused easily. When doing simulations, we can observe many paths and the reader should keep in mind that the *path-bias* will be different for each path. In addition, note that if we assume that σ_t is bounded and bounded away from 0 on $[0, T]$, there is no *bias* in Theorem 1 because $\mathbb{E}[AB_t] = 0$.

Remark 5. (convergence rate) At first glance, the convergence rate α^{-1} looks different from the optimal rate of convergence $n^{1/2}$ we obtain in the no-endogeneity case. This is merely a change of perspective because we are looking from the tick size point-of-view. Actually, if for $k = 1, 2$ we define $N^{(k)}_{t,\alpha}$ as the number of observations before t of the kth asset and the sum of observations of both processes $N^{(S)}_{t,\alpha} := N^{(1)}_{t,\alpha} + N^{(2)}_{t,\alpha}$, we have that $N^{(S)}_{t,\alpha}$ is exactly of order $O_p(\alpha^{-2})$. Thus, if we define the expected number of observations $n := \mathbb{E}\big[N^{(S)}_{t,\alpha}\big]$, we obtain the optimal rate of convergence $n^{\frac{1}{2}}$ in (13).

Remark 6. (robustness to jumps in price processes) We assume that we add a jump component to the price process

$$dX^{(k)}_t = \mu^{(k)}_t dt + \sigma^{(k)}_t dB^{(k)}_t + dJ^{(k)}_t \tag{14}$$

for $k = 1, 2$, where J_t denotes a 2-dimensional finite activity jump process and $dJ^{(k)}_t$ is either zero (no jump) or a real number indicating the size of the jump at time t.

We follow exactly the setting of p. 2 in Andersen et al. (2012). We assume that J_t is a general Poisson process independent of the other quantities. Under the same assumptions the conclusion of Theorem 1 remains valid. The proof can be found in Appendix 8.6. The infinitely many jumps case is complex and beyond the scope of this paper. This was already the case in the 1-dimensional case (see Remark 4 in p. 586 of Li et al. (2014)).

Remark 7. (grid on the original non-log scale) Theorem 1 covers the particular case where X_t corresponds to the log-price and observations are obtained when the price on the original scale hits a boundary. This can be done by a reparametrization of $g_t^{(k)}$ by $\tilde{g}_t^{(k)}(s) := (-\exp(-d_t^{(k)}), \exp(u_t^{(k)}))$.

Remark 8. (arbitrary number of assets) The authors chose for simplicity to work only with two assets, but they conjecture that this result would stay true for an arbitrary number of assets, and that our proofs would adapt to show it, at the cost of more involved notations and definitions.

4.2 Definition of the bias-corrected HY estimator

Assume that we have a consistent estimator[3] $\widehat{AB}_{t,\alpha}$ of the bias $AB_{t,\alpha} := \alpha AB_t$. Such estimator will be provided in Section 5. We define the new estimator $\langle \widehat{X^{(1)}, X^{(2)}} \rangle_{t,\alpha}^{BC}$ of high-frequency covariance as the estimate obtained when removing the bias estimate $\widehat{AB}_{t,\alpha}$ from the Hayashi-Yoshida estimator

$$\langle \widehat{X^{(1)}, X^{(2)}} \rangle_{t,\alpha}^{BC} := \langle \widehat{X^{(1)}, X^{(2)}} \rangle_{t,\alpha}^{HY} - \widehat{AB}_{t,\alpha}. \tag{15}$$

With the bias-corrected estimator $\langle \widehat{X^{(1)}, X^{(2)}} \rangle_{t,\alpha}^{BC}$, we get rid of the asymptotic bias and keep the same asymptotic variance as we can see in the following corollary.

Corollary 2. *Assume* $(A1) - (A4)$*. Then, stably in law as* $\alpha \to 0$*,*

$$\alpha^{-1} \left(\langle \widehat{X^{(1)}, X^{(2)}} \rangle_{t,\alpha}^{BC} - \langle X^{(1)}, X^{(2)} \rangle_t \right) \to \int_0^t (AV_s)^{1/2} \, dZ_s. \tag{16}$$

---

[3] $\widehat{AB}_{t,\alpha}$ is consistent means that $\alpha^{-1}\widehat{AB}_{t,\alpha} = \alpha^{-1} AB_{t,\alpha} + o_p(1)$

4.3 Computation of the theoretical asymptotic bias and asymptotic variance

We warn the reader interested in implementing the bias-corrected estimator that this section is highly technical and we advise her to go directly to Section 5 and refer to this section only for the definitions. On the contrary, if the reader wants to understand the main ideas of the proofs, she should take this section as a reference. We also want to emphasize on the fact that the theoretical values of asymptotic bias and asymptotic variance found at the end of this section are rather abstract and don't shed easily light on how the change of parameters σ_t and g_t in the model would influence the asymptotic bias and asymptotic variance. The main purpose of this paper is that we don't need to know the theoretical values in order to compute the estimators in Section 5.

We need to introduce some definitions in order to compute the theoretical asymptotic bias AB_t and the asymptotic variance term AV_t. We first need to rewrite the HY estimator (7) in a different way. For any positive integer i, consider the ith sampling time of the first asset $\tau_{i-1,\alpha}^{(1)}$. We define two random times, $\tau_{i-1,\alpha}^{-}$ and $\tau_{i-1,\alpha}^{+}$, which are functions of $\tau_{i-1,\alpha}^{(1)}$ and all the observation times of the second asset $\{\tau_{j,\alpha}^{(2)}\}_{j\geq 0}$, and which correspond respectively to the closest sampling time of the second asset that is strictly smaller than $\tau_{i-1,\alpha}^{(1)}$[4], and the closest sampling time of the second asset that is (not necessarily strictly) bigger than $\tau_{i-1,\alpha}^{(1)}$ as

$$\tau_{0,\alpha}^{-} = 0, \tag{17}$$

$$\tau_{i-1,\alpha}^{-} = \max\{\tau_{j,\alpha}^{(2)} : \tau_{j,\alpha}^{(2)} < \tau_{i-1,\alpha}^{(1)}\} \text{ for } i \geq 2, \tag{18}$$

$$\tau_{i-1,\alpha}^{+} = \min\{\tau_{j,\alpha}^{(2)} : \tau_{j,\alpha}^{(2)} \geq \tau_{i-1,\alpha}^{(1)}\} \text{ for } i \geq 1. \tag{19}$$

We consider $\Delta X_{\tau_{i,\alpha}^{-,+}}^{(2)}$ the increment of the second asset between $\tau_{i-1,\alpha}^{-}$ and $\tau_{i,\alpha}^{+}$

$$\Delta X_{\tau_{i,\alpha}^{-,+}}^{(2)} := \Delta X_{[\tau_{i-1,\alpha}^{-},\tau_{i,\alpha}^{+}]}^{(2)}. \tag{20}$$

Rearranging the terms in (7) gives us (except for a few terms at the edge)

$$\widehat{\langle X^{(1)}, X^{(2)}\rangle}_{t,\alpha} = \sum_{\tau_{i,\alpha}^{+}<t} \Delta X_{\tau_{i,\alpha}^{(1)}}^{(1)} \Delta X_{\tau_{i,\alpha}^{-,+}}^{(2)}. \tag{21}$$

---

[4] Connoisseurs will have noticed that $\tau_{i-1,\alpha}^{-}$ is not a $\mathcal{F}_t$-stopping time, which will not be a problem in the proofs

The representation in (21) is very useful in the sense that it gives a natural order between the terms in the sum. Nevertheless, any term of this sum is a priori correlated with the other terms. We will rearrange once again the terms in (21), so that each term is only correlated with the previous and the next term of the sum. In this case, we say that they are *1-correlated.* For this purpose, we need to introduce some notation. We remind the reader that T_α is the two-dimensional vector of sampling times, where for each $k = 1, 2$ the kth component $\mathrm{T}_\alpha^{(k)}$ is equal to the sequence of sampling times associated with the kth asset. We will construct a subsequence T_α^{1C} of $\mathrm{T}_\alpha^{(1)}$ that also depends on the observation times of the second asset $\mathrm{T}_\alpha^{(2)}$, and will be such that we can write the Hayashi-Yoshida estimator as a 1-correlated sum similar to (21), except the new sampling times $\tau_{i,\alpha}^{1C}$ will replace the original observation times $\tau_{i,\alpha}^{(1)}$. The new sampling times $\tau_{i,\alpha}^{1C}$ are obtained using the following algorithm. We define $\tau_{0,\alpha}^{1C} := \tau_{0,\alpha}^{(1)}$, and recursively for i any nonnegative integer

$$\tau_{i+1,\alpha}^{1C} := \min\left\{\tau_{u,\alpha}^{(1)} : \text{ there exists } j \in \mathbb{N} \text{ such that } \tau_{i,\alpha}^{1C} \leq \tau_{j,\alpha}^{(2)} < \tau_{u,\alpha}^{(1)}\right\}. \tag{22}$$

In words, if we sit at the observation time $\tau_{i,\alpha}^{1C}$ of the first asset, we wait first to hit an observation time of the second asset, and we then choose the next strictly bigger observation time of the first asset. In analogy with (17), (18), (19) and (20), we define the following times

$$\begin{aligned}
\tau_{0,\alpha}^{1C,-} &:= 0, & (23)\\
\tau_{i-1,\alpha}^{1C,-} &:= \max\{\tau_{j,\alpha}^{(2)} : \tau_{j,\alpha}^{(2)} < \tau_{i-1,\alpha}^{1C}\} \text{ for } i \geq 2 & (24)\\
\tau_{i-1,\alpha}^{1C,+} &:= \min\{\tau_{j,\alpha}^{(2)} : \tau_{j,\alpha}^{(2)} \geq \tau_{i-1,\alpha}^{1C}\} \text{ for } i \geq 1, & (25)\\
\Delta X_{\tau_{i,\alpha}^{1C,-,+}}^{(2)} &:= \Delta X_{[\tau_{i-1,\alpha}^{1C,-}, \tau_{i,\alpha}^{1C,+}]}^{(2)} \text{ for } i \geq 1. & (26)
\end{aligned}$$

First, observe that, except for maybe a few terms at the edge, we can rewrite (21) as

$$\langle \widehat{X^{(1)}, X^{(2)}} \rangle_{t,\alpha} = \sum_{\tau_{i,\alpha}^{1C,+} < t} \Delta X_{\tau_{i,\alpha}^{1C}}^{(1)} \Delta X_{\tau_{i,\alpha}^{1C,-,+}}^{(2)}. \tag{27}$$

Also, we define the following compensated increments of the HY estimator

$$N_{i,\alpha} = \Delta X_{\tau_{i,\alpha}^{1C}}^{(1)} \Delta X_{\tau_{i,\alpha}^{1C,-,+}}^{(2)} - \int_{\tau_{i-1,\alpha}^{1C}}^{\tau_{i,\alpha}^{1C}} \zeta_s^{1,2} ds. \tag{28}$$

Note that they are compensated in the sense that they are centered (if we decompose $\Delta X^{(2)}_{\tau^{1C,-,+}_{i,\alpha}}$ into a left $(-)$, a central and a right $(+)$ part and condition the expectation, this is straightforward to show). Similarly, we can show that they are 1-correlated.

The idea of the proof is the following. If we consider the volatility matrix σ_t and the grid function g_t to be constant over time, we can express the conditional returns of the normalized error of HY as a homogeneous Markov chain (of order 1), show that the Markov chain is uniformly ergodic and thus use results in the limit theory of Markov chains (see, e.g., Meyn and Tweedie (2009)) to show that it has a stationary distribution. Then, we prove that we can approximate locally the returns of the normalized error when the volatility matrix and grid function are not constant by the returns when holding them constant on a small block. Finally, using limit theory techniques developed in Mykland and Zhang (2012) together with standard probability results of conditional distribution (see, e.g., Breiman (1992)), we can bound uniformly in time the error of the returns when holding the volatility matrix and grid function constant.

Based on the definitions introduced in Appendix 8.1, we can define the *instantaneous variance* of the normalized HY estimate's error (29), which depends on the volatility matrix $\tilde{\sigma}$ and the grid $\tilde{g}$. Similarly, we also define the *instantaneous covariance* between the normalized HY's error and the first asset price (30), and the *instantaneous covariance* between the error and the second asset price (31). Finally, we define the *instantaneous 1-correlated time*, which is the approximation of $\mathbb{E}_{\tau^{1C}_{i,n}}\left[\Delta\tau^{1C}_{i+2}\right]$, where if τ is a $(\mathcal{F}_t)$-stopping time, $\mathbb{E}_\tau\left[Y\right]$ is defined as the conditional distribution of Y given $\mathcal{F}_\tau$.

$$\psi^{AV}(\tilde{\sigma},\tilde{g},x,u) \;:=\; \mathbb{E}\big[\tilde{N}_2^2 + 2\tilde{N}_2\tilde{N}_3\big], \tag{29}$$

$$\psi^{AC1}(\tilde{\sigma},\tilde{g},x,u) \;:=\; \mathbb{E}\big[\tilde{N}_2\Delta\tilde{X}^{(1)}_{\tilde{\tau}^{1C}_2}\big], \tag{30}$$

$$\psi^{AC2}(\tilde{\sigma},\tilde{g},x,u) \;:=\; \mathbb{E}\big[\tilde{N}_2\Delta\tilde{X}^{(2)}_{\tilde{\tau}^{1C,-,+}_2}\big], \tag{31}$$

$$\psi^{\tau}(\tilde{\sigma},\tilde{g},x,u) \;:=\; \mathbb{E}\big[\Delta\tilde{\tau}^{1C}_2\big]. \tag{32}$$

Remark 9. The reader might expect $\tilde{N}_1$ in lieu of $\tilde{N}_2$ in (29), (30), (31) and (32). Actually, we cannot use $\tilde{N}_1$ directly from the definition because the corresponding time $\tilde{\tau}^{1C,-}_0 = 0$. We would need to set it to $-u$ to alter the definition of (29), (30), (31) and (32), which we have chosen not to do for the sake of clarity.

Set $\tilde{Z}_0 := (x, u)$ and for any positive integer i

$$\tilde{Z}_i := \big(\Delta \tilde{X}^{(4)}_{[\tilde{\tau}_i^{1C,-}, \tilde{\tau}_i^{1C}]}, \tilde{\tau}_i^{1C} - \tilde{\tau}_i^{1C,-}\big). \tag{33}$$

For any nonnegative integer i, we consider $\tilde{\pi}_i(\tilde{\sigma}, \tilde{g}, x, u)$ the distribution of $\tilde{Z}_i$. We also introduce the notation $\Pi(\tilde{\sigma}, \tilde{g}, x, u) := \{\tilde{\pi}_i(\tilde{\sigma}, \tilde{g}, x, u)\}_{i \geq 0}$. By the strong Markov property of Brownian motion, we can show that $\tilde{Z}_i$ is a homogeneous Markov chain (of order 1) on the state space $\mathcal{S}_{\tilde{g}}$. In the following lemma, we show that there exists a stationary distribution of $\tilde{\pi}_i(\tilde{\sigma}, \tilde{g}, x, u)$.

Lemma 3. *Let $c := (g^-, g^+, K, d)$ be a four-dimensional vector such that $c \in \mathcal{C}$ and consider $\tilde{\sigma}$ a constant volatility matrix such that $\tilde{\lambda}^{\min} > 0$ and $\tilde{g} \in \mathcal{G}(c)$ a constant grid. Then, there exists a stationary distribution $\tilde{\pi}(\tilde{\sigma}, \tilde{g})$.*

The proof of Lemma 3 can be found in the Appendix (proof of Lemma 14). The next definition is the average (regarding the stationary distributions) of the instantaneous variance, covariances and 1-correlated time. For any $\theta \in \{\text{AV, AC1, AC2}, \tau\}$,

$$\phi^\theta(\tilde{\sigma}, \tilde{g}) := \int_{\mathbb{R}^2} \psi^\theta(\tilde{\sigma}, \tilde{g}, y, v)\, d\tilde{\pi}(\tilde{\sigma}, \tilde{g})(y, v).$$

We introduce the notation $\phi_s^\theta := \phi^\theta(\sigma_s, g_s)$ and consider the following quantities needed to compute the asymptotic bias and variance.

$$k_s^{(1)} := \big(\sigma_s^{(1)}\big)^{-2} \phi_s^{AC1} \big(\phi_s^\tau\big)^{-1}, \tag{34}$$

$$k_s^{1,\perp} := \big(1 - (\rho_s^{1,2})^2\big)^{-1} \big((\sigma_s^{(2)})^{-2} \phi_s^{AC2} - (\sigma_s^{(1)} \sigma_s^{(2)})^{-1} \rho_s^{1,2} \phi_s^{AC1}\big) \big(\phi_s^\tau\big)^{-1}. \tag{35}$$

We express now AV_s the quantity integrated to obtain the asymptotic variance.

$$\begin{aligned} AV_s := & \big(\phi_s^{AV} + 2\big(k_s^{(1)} (\sigma_s^{(1)})^{-1} \sigma_s^{(2)} \rho_s^{1,2} \phi_s^{AC1} - (k_s^{(1)} + k_s^{1,\perp}) \phi_s^{AC2}\big)\big) \big(\phi_s^\tau\big)^{-1} \\ & + \big(\sigma_s^{(1)}\big)^2 \big(k_s^{(1)}\big)^2 + \big(\sigma_s^{(2)}\big)^2 \Big(1 - (\rho_s^{1,2})^2\Big) \big(k_s^{1,\perp}\big)^2. \end{aligned} \tag{36}$$

The asymptotic bias is defined as $AB_t := \int_0^t AB_s^{(1)} dX_s^{(1)} + \int_0^t AB_s^{(2)} dX_s^{(2)}$ where

$$AB_s^{(1)} := k_s^{(1)} - k_s^{1,\perp} \rho_s^{1,2} \sigma_s^{(2)} \big(\sigma_s^{(1)}\big)^{-1}, \tag{37}$$

$$AB_s^{(2)} := k_s^{1,\perp}. \tag{38}$$

Remark 10. (asymptotic bias) Looking at the expressions for $AB_s^{(1)}$ and $AB_s^{(2)}$, one can be tempted to think that because of the $\big(1-(\rho_s^{1,2})^2\big)^{-1}$ term in $k_s^{1,\perp}$, the bias will increase drastically when both assets are highly correlated. In this case, the reader should keep in mind that the second term of $AB_s^{(1)}$, when integrated with respect to $X_s^{(1)}$, and $AB_s^{(2)}$, when integrated with respect to $X_s^{(2)}$, will be roughly of the same magnitude, with opposite signs, and thus there is no explosion of asymptotic bias. We chose the above asymptotic bias' representation because it is straightforward to build estimators from it. We can also express the asymptotic bias differently. For this purpose, we can rewrite the log-price process as

$$\begin{array}{rcl} dX_t^{(1)} & = & \sigma_t^{(1)} dB_t^{(1)}, \\ dX_t^{(2)} & = & \rho_t^{1,2}\sigma_t^{(2)} dB_t^{(1)} + \big(1-(\rho_t^{1,2})^2\big)^{1/2}\sigma_t^{(2)} dB_t^{1,\perp}, \end{array}$$

where $B_t^{(1)}$ and $B_t^{1,\perp}$ are independent Brownian motions. Let

$$dX_t^{1,\perp} = \big(1-(\rho_t^{1,2})^2\big)^{1/2}\sigma_t^{(2)} dB_t^{1,\perp} \tag{39}$$

be the part of $X_t^{(2)}$ that is not correlated with $X_t^{(1)}$. We can express the asymptotic bias as $AB_t = \int_0^t \tilde{AB}_s^{(1)} dX_s^{(1)} + \int_0^t \tilde{AB}_s^{(2)} dB_s^{1,\perp}$. In this case, $\tilde{AB}_s^{(1)} = k_s^{(1)}$ and

$$\tilde{AB}_s^{(2)} = \lim_{n\to\infty} \langle M^n, B^{1,\perp}\rangle_s$$

where M^n is defined in the proofs. We can show that this limit exists, and does not explode when both assets are highly correlated.

5 Estimation of the bias and variance

We need to introduce some new notations. We recall that $N_{1,\alpha}^{(1)}$ is the number of observations corresponding to the first asset before 1 and we also define $N_{1,\alpha}^{1C}$ the number of 1-correlated observations before 1, i.e. $N_{1,\alpha}^{1C} := \max\{i \in \mathbb{N} \text{ s.t. } \tau_{i,\alpha}^{1C} < 1\}$. In practice, the first step is to transform the returns of the first asset

$$\big\{(\Delta X_{\tau_{i,\alpha}^{(1)}}^{(1)}, \Delta\tau_{i,\alpha}^{(1)})\big\}_{i=1}^{N_{1,\alpha}^{(1)}}$$

into 1-correlated returns

$$\big\{(\Delta X_{\tau_{i,\alpha}^{1C}}^{1C}, \Delta\tau_{i,\alpha}^{1C})\big\}_{i=1}^{N_{1,\alpha}^{1C}}$$

using algorithm (22). Then, for each asset, we will chop the data into B_n blocks and on each block $i = 1, \ldots, B_n$ we will estimate $\widehat{AV}_{i,\alpha}$, $\widehat{AB}^{(1)}_{i,\alpha}$ and $\widehat{AB}^{(2)}_{i,\alpha}$, pretending that the volatility matrix σ_t and grid g_t are block-constant.

Because there is asynchronicity in the observation times, the blocks of each asset are not exactly equal. Let h_n be the block size. For the first asset, we consider *block* $1^{(1)} := [0, \tau^{1C}_{h_n,\alpha}]$, *block* $2^{(1)} := [\tau^{1C}_{h_n,\alpha}, \tau^{1C}_{2h_n,\alpha}]$, etc. For the second asset, we let *block* $1^{(2)} := [\tau^{1C,+}_{0,\alpha}, \tau^{1C,+}_{h_n,\alpha}]$, *block* $2^{(2)} := [\tau^{1C,+}_{h_n,\alpha}, \tau^{1C,+}_{2h_n,\alpha}]$, etc. In the following, we will say $j \in$ block $i^{(1)}$ when $\tau^{(1)}_{j,\alpha} \in$ block $i^{(1)}$. Similarly, we say $j \in$ block $i^{(2)}$ when $\tau^{(2)}_{j,n} \in$ block $i^{(2)}$. Finally, we define $j \in$ block i if $j \in \{(i-1)h_n + 1, \ldots, ih_n\}$. First, we estimate the volatility of both assets using the corrected estimator in Li et al. (2014). To do this, we need to define an estimate of the spot volatility on each block for each asset $k = 1, 2$ by

$$\tilde{\sigma}^{(k)}_{i,\alpha} \quad := \quad \Big(\sum_{j \in \text{block } i^{(k)}} (\Delta X^{(k)}_{\tau^{(k)}_{j,\alpha}})^2 \Big)^{1/2}.$$

Then, we estimate the asymptotic bias of the volatility via

$$\widehat{AB\sigma}^{(k)}_{i,\alpha} \quad = \quad \frac{2}{3(\tilde{\sigma}^{(k)}_{i,\alpha})^2} \sum_{j \in \text{block } i^{(1)}} (\Delta X^{(k)}_{\tau^{(k)}_{j,\alpha}})^3.$$

We obtain the bias-corrected estimators of volatility on each block:

$$\hat{\sigma}^{(k)}_{i,\alpha} \quad = \quad \tilde{\sigma}^{(k)}_{i,\alpha} - \widehat{AB\sigma}^{(k)}_{i,\alpha}.$$

Then, we estimate the correlation between both assets using the *naive* HY estimator

$$\hat{\rho}^{1,2}_{i,\alpha} \quad = \quad \frac{1}{\hat{\sigma}^{(1)}_{i,\alpha} \hat{\sigma}^{(2)}_{i,\alpha}} \sum_{j \in \text{block } i} \Delta X^{(1)}_{\tau^{1C}_{j,\alpha}} \Delta X^{(2)}_{\tau^{1C,-,+}_{j,\alpha}}.$$

We then build an estimator of the compensated increments of the HY estimator, following the definition in (28),

$$\widehat{N}_{i,\alpha} \quad = \quad \Delta X^{(1)}_{\tau^{1C}_{i,\alpha}} \Delta X^{(2)}_{\tau^{1C,-,+}_{i,\alpha}} - \Delta \tau^{1C}_{i,\alpha} \hat{\sigma}^{(1)}_{i,\alpha} \hat{\sigma}^{(2)}_{i,\alpha} \hat{\rho}^{1,2}_{i,\alpha}.$$

The next step is to estimate the instantaneous variance (29), both instantaneous covariances (30) and (31) and the instantaneous 1-correlated time (32) on each block. This is done by taking the sample average of the corresponding estimated quantities. Note that we don't directly estimate ψ^{AV}, ψ^{AC1}, ψ^{AC2} and ψ^{τ}, but rather a scaling version of them, i.e. $\alpha_n^2\psi^{AV}$, $\alpha_n\psi^{AC1}$, $\alpha_n\psi^{AC2}$ and $\alpha_n\psi^{\tau}$. In practice, we can always assume $\alpha_n := 1$ by scaling g_t by the tick size, and thus we match the definitions of the following estimators with (29)-(32). For the sake of simplicity, we assume that the number of 1-correlated observations of the last block B_n is also h_n. In practice, this will be most likely different from h_n, and thus the denominator of (40)-(43) will have to be changed so that it is equal to the number of 1-correlated observations in this last block. The estimates are given by

$$\begin{aligned}
\hat{\phi}^{AV}_{i,\alpha} &:= h_n^{-1} \sum_{j \in \text{block } i} \hat{N}^2_{j,\alpha} + 2\hat{N}_{j,\alpha}\hat{N}_{j+1,\alpha}, && (40)\\
\hat{\phi}^{AC1}_{i,\alpha} &:= h_n^{-1} \sum_{j \in \text{block } i} \hat{N}_{j,\alpha}\Delta X^{(1)}_{\tau^{1C}_{j,\alpha}}, && (41)\\
\hat{\phi}^{AC2}_{i,\alpha} &:= h_n^{-1} \sum_{j \in \text{block } i} \hat{N}_{j,\alpha}\Delta X^{(2)}_{\tau^{1C,-,+}_{j,\alpha}}, && (42)\\
\hat{\phi}^{\tau}_{i,\alpha} &:= h_n^{-1} \sum_{j \in \text{block } i} \Delta\tau^{1C}_{j,\alpha}. && (43)
\end{aligned}$$

We estimate now the quantities (34) and (35) as

$$\begin{aligned}
\hat{k}^{(1)}_{i,\alpha} &:= \big(\hat{\sigma}^{(1)}_{i,\alpha}\big)^{-2}\hat{\phi}^{AC1}_{i,\alpha}\big(\hat{\phi}^{\tau}_{i,\alpha}\big)^{-1}, && (44)\\
\hat{k}^{1,\perp}_{i,\alpha} &:= \big(1-(\hat{\rho}^{1,2}_{i,\alpha})^2\big)^{-1}\big((\hat{\sigma}^{(2)}_{i,\alpha})^{-2}\hat{\phi}^{AC2}_{i,\alpha} - (\hat{\sigma}^{(1)}_{i,\alpha}\hat{\sigma}^{(2)}_{i,\alpha})^{-1}\hat{\rho}^{1,2}_{i,\alpha}\hat{\phi}^{AC1}_{i,\alpha}\big)\big(\hat{\phi}^{\tau}_{i,\alpha}\big)^{-1}. && (45)
\end{aligned}$$

We follow (37) and (38) to estimate the bias integrated terms $AB^{(1)}_s$ and $AB^{(2)}_s$ on each block

$$\begin{aligned}
\widehat{AB}^{(1)}_{i,\alpha} &:= \hat{k}^{(1)}_{i,\alpha} - \hat{k}^{1,\perp}_{i,\alpha}\hat{\rho}^{1,2}_{i,\alpha}\hat{\sigma}^{(2)}_{i,\alpha}\big(\hat{\sigma}^{(1)}_{i,\alpha}\big)^{-1},\\
\widehat{AB}^{(2)}_{i,\alpha} &:= \hat{k}^{1,\perp}_{i,\alpha}.
\end{aligned}$$

For the variance term AV_s, we decide not to use the direct definition in (36) because it can provide negative estimates. Instead, we will be using the following estimator

$$\begin{aligned}
\widehat{AV}_{i,\alpha} &:= \Big(\big(\sum_{j \in \text{block } i} \widehat{N}_{j,\alpha}\big) - \hat{k}^{(1)}_{i,\alpha}\big(X^{(1)}_{\tau^{1C}_{ih_n,\alpha}} - X^{(1)}_{\tau^{1C}_{(i-1)h_n,\alpha}}\big)\\
&\quad -\hat{k}^{\perp}_{i,\alpha}\big((X^{(2)}_{\tau^{1C,+}_{ih_n,\alpha}} - X^{(2)}_{\tau^{1C,+}_{(i-1)h_n,\alpha}}) - \hat{\rho}^{1,2}_{i,\alpha}\hat{\sigma}^{(2)}_{i,\alpha}(\hat{\sigma}^{(1)}_{i,\alpha})^{-1}(X^{(1)}_{\tau^{1C}_{ih_n,\alpha}} - X^{(1)}_{\tau^{1C}_{(i-1)h_n,\alpha}})\big)\Big)^2.
\end{aligned}$$

We define the final estimators of asymptotic bias and asymptotic variance as

$$\widehat{AB}_\alpha := \sum_{i=1}^{B_n} \widehat{AB}^{(1)}_{i,\alpha}\big(X^{(1)}_{\tau^{1C}_{ih_n,\alpha}} - X^{(1)}_{\tau^{1C}_{(i-1)h_n,\alpha}}\big) + \widehat{AB}^{(2)}_{i,\alpha}\big(X^{(2)}_{\tau^{1C,+}_{ih_n,\alpha}} - X^{(2)}_{\tau^{1C,+}_{(i-1)h_n,\alpha}}\big), \quad (46)$$

$$\widehat{AV}_\alpha := \sum_{i=1}^{B_n} \widehat{AV}_{i,\alpha}\big(\tau^{1C}_{ih_n,\alpha} - \tau^{1C}_{(i-1)h_n,\alpha}\big). \quad (47)$$

As a corollary of Theorem 1, we obtain the following result, which states the consistency of (46) and (47).

Corollary 4. *There exists a choice of the block size* h_n[5] *such that when* $\alpha \to 0$*, we have*

$$\alpha^{-1}\widehat{AB}_\alpha \overset{\mathbb{P}}{\to} AB_1, \quad (48)$$

$$\alpha^{-2}\widehat{AV}_\alpha \overset{\mathbb{P}}{\to} \int_0^1 AV_s ds. \quad (49)$$

In particular, in view of Corollary 2, the bias-corrected estimator $\widehat{\langle X^{(1)}, X^{(2)}\rangle}^{BC}_{1,\alpha} := \widehat{\langle X^{(1)}, X^{(2)}\rangle}^{HY}_{1,\alpha} - \widehat{AB}_\alpha$ *is such that*

$$\frac{\widehat{\langle X^{(1)}, X^{(2)}\rangle}^{BC}_{1,\alpha} - \langle X^{(1)}, X^{(2)}\rangle_1}{\widehat{AV}_\alpha^{1/2}} \to \mathcal{N}(0,1). \quad (50)$$

Remark 11. (exchanging $X^{(1)}_t$ and $X^{(2)}_t$) When estimating the asymptotic bias and the asymptotic variance, we considered one specific asset to be $X^{(1)}_t$ and the other one to be $X^{(2)}_t$. We could exchange $X^{(1)}_t$ and $X^{(2)}_t$, and find new estimators $\tilde{A}B_\alpha$ and $\tilde{A}V_\alpha$ according to the previous definitions. One could then take $\frac{AB_\alpha + \tilde{A}B_{t,\alpha}}{2}$ (respectively $\frac{AV_\alpha + \tilde{A}V_{t,\alpha}}{2}$) as final estimators of asymptotic bias (asymptotic variance).

Remark 12. (optimal block size) In practice, the optimal block size h_n is not straightforward to choose. On the one hand, h_n should be as small as possible so that the volatility matrix σ_t and the grid g_t are almost constant on each block, and thus (40)-(43) are less biased. On the other hand, we need as many observations as we can on each block, so that the variance of approximations (40)-(43) is not too big. We are facing here the usual bias-variance tradeoff.

---

[5] the exact assumptions on h_n can be found in the proofs of Theorem 1

6 Numerical simulations

We consider four different settings in this part. We describe here the first one. We assume the same setting as the toy model described in Example 1, in two dimensions. Thus, there exists a four-dimensional parameter $\theta := (\theta_u^{(1)}, \theta_d^{(1)}, \theta_u^{(2)}, \theta_d^{(2)})$ such that for any $t \geq 0$ and any $s \geq 0$, $u_t^{(1)}(s) := \theta_u^{(1)}$, $d_t^{(1)}(s) := \theta_d^{(1)}$, $u_t^{(2)}(s) := \theta_u^{(2)}$ and $d_t^{(2)}(s) := \theta_d^{(2)}$. We assume that the two-dimensional price process $(X_t^{(1)}, X_t^{(2)})$ has a null-drift. Also, we assume that the volatility of the first process is $\sigma_t^{(1)} := \tilde{\tilde{\sigma}}^{(1)}$ where $\tilde{\tilde{\sigma}}^{(1)} := 0.016$ and the volatility of the second process $\sigma_t^{(2)} := \tilde{\tilde{\sigma}}^{(2)}$ where $\tilde{\tilde{\sigma}}^{(2)} := 0.02$, and that the correlation between both assets is $\rho_t^{1,2} := 0.2$. We set $\theta := \big(0.0007, 0.0001, 0.0006, 0.0001\big)$. According to this rule, a change of price occurs whenever the price of the first (respectively second) asset increases by 0.07% (0.06%) or decreases by 0.01% (0.01%). Finally, we assume that the price processes $(X_t^{(1)}, X_t^{(2)})$ and the time processes $(X_t^{(t,1)}, X_t^{(t,2)})$ are equal.

The second setting is similar to the first setting, except that we assume now a stochastic volatility Heston model. Specifically, we assume that

$$\begin{aligned} dX_t^{(k)} &:= \mu^{(k)} dt + \sigma_t^{(k)} dB_t^{(k)}, \\ d(\sigma_t^{(k)})^2 &:= \kappa^{(k)} \big((\tilde{\tilde{\sigma}}^{(k)})^2 - (\sigma_t^{(k)})^2 \big) dt + \delta^{(k)} \sigma_t^{(k)} d\tilde{\tilde{B}}_t^{(k)}, \end{aligned}$$

where the constant high-frequency covariance between $B_t^{(k)}$ and $\tilde{\tilde{B}}_t^{(k)}$ is fixed to $\tilde{\tilde{\rho}}^{(k)}$, and $(\tilde{\tilde{B}}_t^{(1)}, \tilde{\tilde{B}}_t^{(2)})$ are uncorrelated with each other. We choose to work with drift $(\mu^{(1)}, \mu^{(2)}) := (0.03, 0.02)$, and to add leverage effect $(\tilde{\tilde{\rho}}^{(1)}, \tilde{\tilde{\rho}}^{(2)})$ are selected to be $(-0.8, -0.7)$. Finally, $(\kappa^{(1)}, \kappa^{(2)}) := (4.5, 5.5)$, the volatility of volatility $(\delta^{(1)}, \delta^{(2)}) := (0.4, 0.5)$, and the volatility starting values $(\sigma_0^{(1)}, \sigma_0^{(2)}) := (\tilde{\tilde{\sigma}}^{(1)}, \tilde{\tilde{\sigma}}^{(2)})$.

We consider now the third setting, which goes one step further than the previous setting. We assume a jump-diffusion model for both the price and the volatility. Formally, we assume that

$$\begin{aligned} dX_t^{(k)} &:= \mu^{(k)} dt + \sigma_t^{(k)} dB_t^{(k)} + dJ_t^{(k)}, \\ d(\sigma_t^{(k)})^2 &:= \kappa^{(k)} \big((\tilde{\tilde{\sigma}}^{(k)})^2 - (\sigma_t^{(k)})^2 \big) dt + \delta^{(k)} \sigma_t^{(k)} d\tilde{\tilde{B}}_t^{(k)} + d\tilde{J}_t^{(k)}, \end{aligned}$$

where the jumps $(J_t^{(1)}, J_t^{(2)}, \tilde{J}_t^{(1)}, \tilde{J}_t^{(2)})$ follow a 4-dimensional Poisson process with intensity $(\lambda^{(1)}, \lambda^{(2)}, \tilde{\lambda}^{(1)}, \tilde{\lambda}^{(2)}) := (12, 11, 10, 9)$. The jump sizes are taken to be 1 or -1

with probability $\frac{1}{2}$ for price processes, and 0.0001 or -0.0001 with half-probability for volatility processes.

In the fourth setting, we consider another model of arrival times, namely Example 4. We set the tick size $\alpha = 0.0001$ and the friction parameter $\eta = 0.15$. Price and volatility processes are assumed to follow the same model as in the second setting.

We simulate price processes and observation times for 10 years of 252 business days. We choose $h_n = n^{\frac{1}{2}}$ for Settings 2 to 4. We provide in Table 1 a summary of the comparison results between HY and the bias-corrected HY. As expected from the theory, the RMSE is improved when using the bias-corrected estimator in Example 1. In Example 4, the bias-corrected HY doesn't seem to perform better than HY. We conjecture that there is no asymptotic bias in Example 4, and that this is the reason why we don't observe any difference between the two estimators in that simple model. In addition, the sample bias is almost the same when using HY and the bias-corrected estimator for the four different settings, which is also expected from Remark 4. Furthermore, this sample bias tends to 0, which comes from the fact that both estimators are consistent. Finally, the standardized feasible statistic (50) in the first setting is reported in Table 2 and plotted in Figure 2.

7 Conclusion

We have introduced in this paper the HBT model, and we have shown that it is more general than some of the endogenous models of the literature. This model can be extended to a model including more general noise structure in observations, and even noise in sampling times. This is investigated in Potiron (2016).

Under this model, we have proved the central limit theorem of the Hayashi-Yoshida estimator. Our main theorem states that there is an asymptotic bias. Accordingly, we built a bias-corrected HY estimator. We also computed the theoretical standard deviation, and we provided consistent estimates of it. Numerical simulations corroborate the theory.

The techniques used for the proof of the main theorem could be applied to more general models and to other problems such as the estimation of the integrated variance of noise, integrated betas, etc. In particular, independence between the efficient price process and the noise is not needed in the model. As long as we can approximate the joint distribution of the noise and the returns by a Markov chain, ideas of our proof can be used.

8 Appendix

8.1 Definition of some quantities of approximation

We define in this section some quantities assuming the volatility matrix σ_t and the grid function g_t are constant. For that purpose, let $\tilde{W}_t$ be a four dimensional Wiener process, $c := (g^-, g^+, K, d)$ a four-dimensional vector such that $c \in \mathcal{C}$ and $\tilde{\sigma}$ a constant volatility matrix such that the associated $\tilde{\lambda}^{\min}$, which is the analog of $\lambda_t^{\min}$ defined in Section 4.1 when we replace σ_t by $\tilde{\sigma}$, is stritcly bigger than 0 and $\tilde{g} \in \mathcal{G}(c)$ a constant grid function. In analogy with the definition of the grid function g_t in $(A3)$, we assume that $\tilde{g}$ can be written in terms of the down and up functions of both assets, i.e. $\tilde{g} := (\tilde{g}^{(1)}, \tilde{g}^{(2)})$ where for each $k = 1, 2$ we have $\tilde{g}^{(k)} := (\tilde{d}^{(k)}, \tilde{u}^{(k)})$. Also, we introduce $\mathcal{S}_{\tilde{g}}$ the subspace of $\mathbb{R}^2$ defined as

$$\mathcal{S}_{\tilde{g}} := \{(y, v) \in \mathbb{R} \times \mathbb{R}^+ \text{ s.t. } \tilde{d}^{(2)}(v) \leq y \leq \tilde{u}^{(2)}(v)\}.$$

If we set $\tilde{X} = \tilde{\sigma}\tilde{W}$ and the corresponding sampling times of both assets $\tilde{\mathrm{T}} := (\tilde{\mathrm{T}}^{(1)}, \tilde{\mathrm{T}}^{(2)})$, where for $k = 1, 2$ we have $\tilde{T}^{(k)} := \{\tilde{\tau}_i\}_{i \geq 0}$, we define the observation times of the first asset as $\tilde{\tau}_0^{(1)} := 0$ and recursively for i any positive integer

$$\tilde{\tau}_i^{(1)} := \inf\left\{t > \tilde{\tau}_{i-1}^{(1)} : \Delta\tilde{X}_t^{(3)} \notin [\tilde{d}^{(1)}(t - \tilde{\tau}_{i-1}^{(1)}), \tilde{u}^{(1)}(t - \tilde{\tau}_{i-1}^{(1)})]\right\}.$$

These stopping times will be seen as approximations of the observation times of the first asset when we hold the volatility matrix σ_t and the grid g_t constant. We will always start our approximation at a *1-correlated* observation time $\tau_{i,n}^{1C}$, which corresponds to an observation time of the first asset. As the sampling times of the second asset are not synchronized with the ones from the first asset, we need two more quantities $(x, u) \in \mathcal{S}_{\tilde{g}}$ to approximate the observation times of the second asset. They correspond respectively to the increment of the second asset's time process $X_t^{(t,2)}$ since the last observation of the second asset occured and the time elapsed since the last observation time of the second asset. We define $\tilde{\tau}_0^{(2)} := 0$,

$$\tilde{\tau}_1^{(2)} := \inf \big\{ t > 0 : x + \Delta \tilde{X}_t^{(4)} \notin [\tilde{d}_2(t+u), \tilde{u}_2(t+u)] \big\},$$

and for any integer $i \geq 2$

$$\tilde{\tau}_i^{(2)} := \inf \big\{ t > \tilde{\tau}_{i-1}^{(2)} : \Delta \tilde{X}_t^{(4)} \notin [\tilde{d}_2(t - \tilde{\tau}_{i-1}^{(2)}), \tilde{u}_2(t - \tilde{\tau}_{i-1}^{(2)})] \big\}.$$

Similarly, we define the analogs of (17)-(18), (19), (20), (22), (23)-(24), (25), (26) and (28) respectively as $\tilde{\tau}_{i-1}^{-}$, $\tilde{\tau}_{i-1}^{+}$, $\Delta \tilde{X}^{(2)}_{\tilde{\tau}_i^{-,+}}$, $\tilde{\tau}_{i-1}^{1C,-}$, $\tilde{\tau}_{i-1}^{1C,+}$, $\Delta \tilde{X}^{(2)}_{\tilde{\tau}_i^{1C,-,+}}$ and $\tilde{N}_i$ by putting tildes on the quantities in the definitions.

8.2 Preliminary lemmas

Without loss of generality, we choose to work under the third scenario defined in Section 2.4, i.e. the asset price is different from the time process for both assets. Because we shall prove stable convergence, and because of the local boundedness of σ (because by (A1) σ is continuous), and that $\inf_{t \in (0,1]} \lambda_t^{\min} > 0$ we can without loss of generarality assume that for all $t \in [0,1]$ there exists some nonrandom constants σ^- and σ^+ such that for any eigen-value λ_t of σ_t we have

$$0 < \sigma^- < \lambda_t < \sigma^+, \tag{51}$$

by using a standard localization argument such that the one used in Section 2.4.5 of Mykland and Zhang (2012). One can further supress μ as in Section 2.2 (pp. 1407-1409) of Mykland and Zhang (2009), and act as if X is a martingale.

We define the subspace $\mathcal{M}$ of matrices of dimension 4×4 such that $\forall M \in \mathcal{M}$, for any eigen-value λ_M of M, we have

$$\sigma^- < \lambda_M < \sigma^+ \tag{52}$$

and $\frac{\left(MM^T\right)^{3,4}}{(MM^T)^{4,4}} \in [\rho_-^{3,4}, \rho_+^{3,4}]$. By (8) of $(A2)$ and (51), we will assume in the following that $\forall t \in [0,1]$, $\sigma_t \in \mathcal{M}$.

We define σ^p the process (of dimension 4×4) on $\mathbb{R}^+$ such that

$$\begin{cases} \sigma_t^p &= \sigma_t \quad \forall t \in [0,1], \\ \sigma_t^p &= \sigma_1 \quad \forall t \in [1,\infty). \end{cases}$$

Define now X^p the process such that for all $t \geq 0$

$$\begin{cases} dX_t^p &= \sigma_t^p dW_t, \\ X_0^p &= X_0. \end{cases}$$

Because X^p and X have the same initial value and follow the same stochastic differential equation on $[0,1]$, they are equal for all $t \in [0,1]$. For simplicity, we keep from now on the notation X for X^p.

In the following, C will be defining a constant which does not depend on i or n, but that can vary from a line to another. Also, we are going to use the notation $\tau_{i,n}^{\theta}$ as a subtitute of $\tau_{i,\alpha_n}^{\theta}$, where θ can take various names, such that $(1), (2)$ and so on. Let $h : \mathbb{N} \to \mathbb{N}$ a (not strictly) increasing non-random sequence such that

$$h_n \to +\infty, \tag{53}$$

$$h_n \alpha_n \to 0. \tag{54}$$

To keep notation as simple as possible, we define $\tau_{i,n}^{h} := \tau_{ih_n,n}^{1C}$, $\tau_{i,n}^{h,-} := \tau_{ih_n,n}^{1C,-}$, $\tau_{i,n}^{h,+} := \tau_{ih_n,n}^{1C,+}$. We also let $A_n := \{i \geq 1 \text{ s.t. } \tau_{i-1,n}^{h} \leq t\}$, where $t \in [0,1]$. Also, we recall the notation $(X_t^{(3)}, X_t^{(4)}) := (X_t^{(t,1)}, X_t^{(t,2)})$ Finally, for $\theta \in \{(1),(2),1C,h\}$, we define $s_n^{\theta} = \sup\limits_{\tau_{i,n}^{\theta} < T} \Delta \tau_{i,n}^{\theta}$. We show that these quantities tend to 0 almost surely in the following lemma.

Lemma 5. *We have* $s_n^{\theta} \overset{a.s.}{\to} 0$.

Proof. We can follow the proof of Lemma 4.5 in Robert and Rosenbaum (2012) to prove that for $k \in \{1,2\}$, $s_n^{(k)} \overset{a.s.}{\to} 0$. Then, we can notice that a.s. $s_n^{1C} < s_n^{(1)} + s_n^{(2)}$ to deduce that $s_n^{1C} \overset{a.s.}{\to} 0$. To show that $s_n^{h} \to 0$, define the process Z such that $Z_0 = 0$ and $\forall i > 0$ we have

$$Z_t := \begin{cases} \Delta X^{(2)}_{[\tau_{i-1,n}^{1C}, t]} + Z_{\tau_{i-1,n}^{1C}} & \forall t \in [\tau_{i-1,n}^{1C}, \tau_{i-1,n}^{1C,+}], \\ \Delta X^{(1)}_{[\tau_{i-1,n}^{1C,+}, t]} + Z_{\tau_{i-1,n}^{1C,+}} & \forall t \in [\tau_{i-1,n}^{1C,+}, \tau_{i,n}^{1C}]. \end{cases}$$

Substituting X in Lemma 4.5 of Robert and Rosenbaum's proof by our Z, we can follow the same reasoning. The only main change will be that in their notation $M_n \leq C h_n \alpha_n$, but this tends to 0 by (54). $\square$

Let f be a random process, s a random number, we define

$$S(f,s) := \sup_{0\leq u,v\leq 1, |u-v|\leq s} \Big| f_u - f_v \Big| .$$

Lemma 6. *Let f be a bounded random process such that for all non-random sequence $(q_n)_{n\geq 0}$, if $q_n \to 0$, then $S(f,q_n) \xrightarrow{\mathbb{P}} 0$. Let also a random sequence $(s_n)_{n\geq 0}$ such that $s_n \xrightarrow{\mathbb{P}} 0$. Then we have $\forall l \geq 1$ that*

$$S(f,s_n) \xrightarrow{\mathbf{L}^l} 0.$$

Proof. As f is bounded, convergence in $\mathbb{P}$ implies convergence in $\mathbf{L}^l$ for any $l \geq 1$. Hence it is sufficient to show that $S(f,s_n) \xrightarrow{\mathbb{P}} 0$. Let $\eta > 0$ and $\epsilon > 0$, we want to show that $\exists N > 0$ such that $\forall n \geq N$, we have

$$\mathbb{P}(S(f,s_n) > \eta) < \epsilon.$$

$\exists$ non-random $\chi > 0$ such that $\mathbb{P}(S(f,\chi) > \eta) < \frac{\epsilon}{2}$. Also, $\exists N > 0$ such that $\forall n \geq N$, $\mathbb{P}(s_n \geq \chi) < \frac{\epsilon}{2}$. Thus

$$\begin{aligned} \mathbb{P}(S(f,s_n) > \eta) &= \mathbb{P}(S(f,s_n) > \eta, s_n > \chi) + \mathbb{P}(S(f,s_n) > \eta, s_n \leq \chi) \\ &\leq \mathbb{P}(s_n > \chi) + \mathbb{P}(S(f,\chi) > \eta) < \epsilon. \end{aligned}$$

□

We aim to define the approximations of observation times on blocks

$$\left(K_{i,n} := [\tau^h_{i,n}, \tau^h_{i+1,n}]\right)_{i\geq 0}.$$

We need some definitions first. Let $(C^{(i)}_t)_{i\geq 0}$ a sequence of independent 4-dimensional Brownian motions (i.e. for each i, $C^{(i)}_t$ is a 4-dimensional Brownian motion), independent of everything we have defined so far. We define $\forall i, n \geq 0$,

$$S^{i,n}_t := \begin{cases} \Delta W_{[\tau^h_{i,n}, \tau^h_{i,n} + \cdot]} & \forall t \in [0, \Delta\tau^h_{i+1,n}], \\ \Delta W_{[\tau^h_{i,n}, \tau^h_{i+1,n}]} + C^{(i)}_{t-\Delta\tau^h_{i+1,n}} & \forall t \geq \Delta\tau^h_{i+1,n}, \end{cases}$$

and

$$\left(\tilde{\tau}^k_{i,j,n}\right)_{j\geq 0; k=1,2} = \tilde{\mathrm{T}}\left(S^{i,n}, \sigma_{\tau^h_{i,n}}, \alpha_n g_{\tau^h_{i,n}}, \Delta X^{(4)}_{[\tau^{h,-}_{i,n}, \tau^h_{i,n}]}, \tau^h_{i,n} - \tau^{h,-}_{i,n}\right).$$

To keep symmetry in notations, we define for all integers i and n positive integers, $\left(\tau^{(1)}_{i,j,n}\right)_{j\geq 0}$ consisting of the observation times of the process 1 after $\tau^h_{i,n}$, substracting the value of $\tau^h_{i,n}$, i.e. $\tau^{(1)}_{i,j,n} = \tau^{(1)}_{i^*+j,n} - \tau^{(1)}_{i^*,n}$ where i^* is the (random) index on the original grid of process 1 corresponding to $\tau^h_{i,n}$ ($\tau^{(1)}_{i^*,n} = \tau^h_{i,n}$). For process 2, we define $\tau^{(2)}_{i,0,n} = 0$ and for integers $j \geq 1$, $\tau^{(2)}_{i,j,n} = \tau^{(2)}_{j^*+j-1,n} - \tau^{(1)}_{i^*,n}$, where j^* is the index on the original grid of process 2 corresponding to the smallest observation time of process 2 bigger (not necessarily strictly) than $\tau^h_{i,n}$. We also define $\tau^-_{i,j,n}$, $\tau^+_{i,j,n}$, $\tau^{1C}_{i,j,n}$, $\tau^{1C,-}_{i,j,n}$, $\tau^{1C,+}_{i,j,n}$, $\tilde{\tau}^-_{i,j,n}$, $\tilde{\tau}^+_{i,j,n}$, $\tilde{\tau}^{1C}_{i,j,n}$, $\tilde{\tau}^{1C,-}_{i,j,n}$, $\tilde{\tau}^{1C,+}_{i,j,n}$ following the construction we used to define (17), (18), (19), (22), (23), (24) and (25). We also set

$$\left(\tilde{\pi}_{i,j,n}\right)_{j\geq 0} = \mathit{\Pi}\left(S^{i,n}, \sigma_{\tau^h_{i,n}}, \alpha_n g_{\tau^h_{i,n}}, \Delta X^{(4)}_{[\tau^{h,-}_{i,n},\tau^h_{i,n}]}, \tau^h_{i,n} - \tau^{h,-}_{i,n}\right).$$

Lemma 7. *For $\theta \in \{(1),(2),1C\}$, any real $l > 0$, any positive integer i and n, any non-negative integer j, we have $0 < C^-_l < C^+_l$ such that*

$$C^-_l \alpha_n^{2l} < \mathbb{E}\left[\left(\Delta\tilde{\tau}^{\theta}_{i,j,n}\right)^l\right] \leq C^+_l \alpha_n^{2l}, \tag{55}$$

where $\Delta\tilde{\tau}^{\theta}_{i,j,n} := \tilde{\tau}^{\theta}_{i,j,n} - \tilde{\tau}^{\theta}_{i,j-1,n}$ and

$$C^-_l \alpha_n^{2l} < \mathbb{E}\left[\left(\Delta\tau^{(k)}_{i,n}\right)^l\right] \leq C^+_l \alpha_n^{2l}. \tag{56}$$

Proof. For $\theta \in \{(1),(2)\}$, because of (7) and (51), we can deduce (55) using well-known result on exit zone of a Brownian motion (see for instance Borodin and Salminen (2002)). (56) can be deduced using Dubins-Schwarz theorem for continuous local martingale (see, e.g. Th. V.1.6 in Revuz and Yor (1999)). If $\theta = 1C$ writing $\Delta\tilde{\tau}^{\theta}_{i,j,n} = \left(\tilde{\tau}^{\theta,+}_{i,j-1,n} - \tilde{\tau}^{\theta}_{i,j-1,n}\right) + \left(\tilde{\tau}^{\theta,+}_{i,j,n} - \tilde{\tau}^{\theta,+}_{i,j-1,n}\right)$ and working those two terms, we can obtain (55) and (56). □

Now, we define for $\theta \in \{(1),(2),1C,h\}$ the number of observation times before t as

$$N^{\theta}_{t,n} = \sup\{i : \tau^{\theta}_{i,n} < t\}.$$

We have the following lemma

Lemma 8. *For $\theta \in \{(1),(2),1C\}$, we have that the sequence $\left(\alpha_n^2 N^{\theta}_{t,n}\right)_{n\geq 1}$ is tight.*

Proof. Here for $\theta \in \{(1),(2)\}$ we can follow the proof of Lemma 4.6 in Robert and Rosenbaum (2012) together with Lemma 5. Also, by definition we have $N_{t,n}^{1C} \leq N_{t,n}^{(1)}$ so we also deduce the tightness of $\left(\alpha_n^2 N_{t,n}^{1C}\right)_{n\geq 1}$. □

Lemma 9. *Let* $(U_{i,n})_{i,n\geq 1}$ *an array of positive random variables and* $\theta \in \{(1),(2),1C\}$. *If*

$$\forall u > 0, \quad \textstyle\sum_{i=1}^{\llcorner u\alpha_n^{-2}\lrcorner} U_{i,n} \xrightarrow{\mathbb{P}} 0 \tag{57}$$

then $\sum_{i=1}^{N_{t,n}^{\theta}} U_{i,n} \xrightarrow{\mathbb{P}} 0$. *Also, if* $\forall u > 0$, $\sum_{i=1}^{\llcorner u\alpha_n^{-2}h(n)^{-1}\lrcorner} U_{i,n} \xrightarrow{\mathbb{P}} 0$, *then* $\sum_{i=1}^{N_{t,n}^{h}} U_{i,n} \xrightarrow{\mathbb{P}} 0$.

Proof. Let $\epsilon > 0$ and $u > 0$.

$$\begin{aligned}
\mathbb{P}\left(\sum_{i=1}^{N_{t,n}^{\theta}} U_{i,n} > \epsilon\right) &= \mathbb{P}\Bigg(\sum_{i=1}^{\llcorner u\alpha_n^{-2}\lrcorner} U_{i,n} + \sum_{i=\llcorner u\alpha_n^{-2}\lrcorner+1}^{N_{t,n}^{\theta}} U_{i,n}\mathbf{1}_{\{\llcorner u\alpha_n^{-2}\lrcorner < N_{t,n}^{\theta}\}} \\
&\qquad - \sum_{i=N_{t,n}^{\theta}+1}^{\llcorner u\alpha_n^{-2}\lrcorner} U_{i,n}\mathbf{1}_{\{\llcorner u\alpha_n^{-2}\lrcorner > N_{t,n}^{\theta}\}} > \epsilon\Bigg) \\
&\leq \mathbb{P}\left(\sum_{i=1}^{\llcorner u\alpha_n^{-2}\lrcorner} U_{i,n} + \sum_{i=\llcorner u\alpha_n^{-2}\lrcorner+1}^{N_{t,n}^{\theta}} U_{i,n}\mathbf{1}_{\{\llcorner u\alpha_n^{-2}\lrcorner < N_{t,n}^{\theta}\}} > \epsilon\right) \\
&\leq \mathbb{P}\left(\sum_{i=1}^{\llcorner u\alpha_n^{-2}\lrcorner} U_{i,n} > \frac{\epsilon}{2}\right) + \mathbb{P}\left(\sum_{i=\llcorner u\alpha_n^{-2}\lrcorner+1}^{N_{t,n}^{\theta}} U_{i,n}\mathbf{1}_{\{\llcorner u\alpha_n^{-2}\lrcorner < N_{t,n}^{\theta}\}} > \frac{\epsilon}{2}\right) \\
&\leq \mathbb{P}\left(\sum_{i=1}^{\llcorner u\alpha_n^{-2}\lrcorner} U_{i,n} > \frac{\epsilon}{2}\right) + \mathbb{P}\left(\llcorner u\alpha_n^{-2}\lrcorner < N_{t,n}^{\theta}\right).
\end{aligned}$$

We take the $\limsup\limits_{n\to\infty}$ and use (57). We obtain

$$\limsup_{n\to\infty} \mathbb{P}\left(\sum_{i=1}^{N_{t,n}^{\theta}} U_{i,n} > \epsilon\right) \leq \limsup_{n\to\infty} \mathbb{P}\left(\llcorner u\alpha_n^{-2}\lrcorner < N_{t,n}^{\theta}\right).$$

We now tend $u \to \infty$ and conclude using Lemma 8. The second statement is proved in the same way. □

Lemma 10. *For any $\alpha > 0$, $\sigma \in \mathcal{M}, g \in \mathcal{G}, (x,u) \in \mathcal{S}_g$, we have that*

$$\begin{aligned}
\psi^{AV}(\sigma,g,x,u) &= \alpha^{-4}\psi^{AV}\left(\sigma,\alpha g,\alpha x,\alpha^2 u\right),\\
\psi^{AC1}(\sigma,g,x,u) &= \alpha^{-3}\psi^{AC1}\left(\sigma,\alpha g,\alpha x,\alpha^2 u\right),\\
\psi^{AC2}(\sigma,g,x,u) &= \alpha^{-3}\psi^{AC2}\left(\sigma,\alpha g,\alpha x,\alpha^2 u\right),\\
\psi^{\tau}(\sigma,g,x,u) &= \alpha^{-2}\psi^{\tau}\left(\sigma,\alpha g,\alpha x,\alpha^2 u\right).
\end{aligned}$$

Proof. For any Brownian motion $(W_t)_{t\geq 0}$, by the scale property we have that $(W_t)_{t\geq 0} \overset{\mathcal{L}}{=} (\alpha^{-1}W_{\alpha^2 t})_{t\geq 0}$. Thus, if we define $\tau = \inf\{t > 0 \text{ s.t. } W_t \notin [d(t),u(t)]\}$ and $\tau_\alpha = \inf\{t > 0 \text{ s.t. } W_t \notin [\alpha d(t),\alpha u(t)]\}$, we have that

$$\tau \overset{\mathcal{L}}{=} \inf\{t > 0 \text{ s.t. } W_{\alpha^2 t} \notin [\alpha d(t),\alpha u(t)]\} \overset{\mathcal{L}}{=} \alpha^{-2}\tau_\alpha.$$

We deduce that

$$(\tau, W_\tau) \overset{\mathcal{L}}{=} \left(\alpha^{-2}\tau_\alpha, W_{\alpha^{-2}\tau_\alpha}\right) \overset{\mathcal{L}}{=} \left(\alpha^{-2}\tau_\alpha, \alpha W_{\tau_\alpha}\right). \tag{58}$$

We can prove the lemma based on the way we proved (58), at the cost of 2-dimension definitions that would be more involved and straightforward applications of Strong Markov property of Brownian motions that we won't write, so that we don't lose ourselves in the technicality of this proof. □

We introduce the number of points in the ith block in the kth process as the following

$$N_{i,n}^{(k)} = \max\{j \geq 0 \text{ s.t. } \tau_{i,n}^h + \tau_{i,j,n}^{(k)} \leq \tau_{i+1,n}^h\}.$$

We also introduce the total number of points in the ith block $N_{i,n} = N_{i,n}^{(1)} + N_{i,n}^{(2)}$. We show now that we can control uniformly the error of the approximations of the observation times.

Lemma 11. *Let $l \geq 1$, we have that*

$$\sup_{i\geq 0\ ,\ 2\leq j\leq h_n} \mathbb{E}\left[\left|\Delta\tau_{i,j,n}^{1C} - \Delta\tilde{\tau}_{i,j,n}^{1C}\right|^l\right] = o_p\left(\alpha_n^{2l}\right) \tag{59}$$

and

$$\sup_{i\geq 0\ ,\ 2\leq j\leq h_n} \mathbb{E}\left[\left|\Delta\tau_{i,j,n}^{1C,-,+} - \Delta\tilde{\tau}_{i,j,n}^{1C,-,+}\right|^l\right] = o_p\left(\alpha_n^{2l}\right). \tag{60}$$

Proof. We introduce the notation o_p^U where U stands for "uniformly in $i \geq 0$", meaning that the sup of the rests is of the given order

First step : We define $\tilde{s}_n^h = \sup\limits_{i \in A_n} \tilde{\tau}_{i,h_n,n}^{1C}$. We show in this step that

$$\tilde{s}_n^h \xrightarrow{\mathbb{P}} 0. \tag{61}$$

We define the accumulated time of approximated durations, i.e.

$$\tilde{\tau}_{i,n}^h = \sum_{l=0}^{l=i} \tilde{\tau}_{l,h_n,n}^{1C}.$$

Using Lemma 7 together with Lemma 8, $\exists M > 0$ such that

$$\mathbb{P}\left(\tilde{\tau}_{N_n^h,n}^h \leq M\right) \to 1.$$

We define $Z_0^n = 0$ and $\forall t \in [\tilde{\tau}_{i-1,n}^h, \tilde{\tau}_{i,n}^h]$,

$$Z_t^n = Z_{\tilde{\tau}_{i-1,n}^h}^n + S_{t-\tilde{\tau}_{i-1,n}^h}^{i-1,n}.$$

A slight modification of the proof of Lemma 5 will conclude.

Second step : We show that we can do a localization in the number of observations in the i-th block, i.e. there exists a non-random M_n such that

$$\mathbb{P}\left(\max\left(N_{i,n}^{(1)}, N_{i,n}^{(2)}\right) > M_n\right) \tag{62}$$

converges uniformly (in i) towards 0 and M_n increasing at most linearly with h_n, i.e. we have $M_n \leq \beta h_n$ where $\beta > 0$.

To prove (62), we need some definitions. Define for $i \geq 0$ the order of observation times $O_{i,k,n}$ and the order of the approximated observation times $\tilde{O}_{i,k,n}$ in the following way. Let $\mathrm{T}_{i,n}^O := \left(\tau_{i,j,n}^O\right)_{j \geq 0}$ the sorted set of all observation times (corresponding to process 1 and 2) strictly greater than $\tau_{i,n}^h$. Then for $j \geq 1$, we will set $O_{i,j,n} = 1$ if the j-th observation time in $\mathrm{T}_{i,n}^O$ corresponds to an observation of the first process and $O_{i,j,n} = 2$ if it corresponds to an observation of the second process. Similarly, we set

$\tilde{\mathrm{T}}^{O}_{i,n}$ the sorted set of all approximated times $\left(\tilde{\tau}^{(k)}_{i,j,n}\right)_{j\geq 0, k=1,2}$. $\tilde{O}_{i,j,n}$ are defined in the same way. There exists a $p > 0$ such that for all integers i, j, n :

$$\mathbb{P}\left(O_{i,j+1,n} = 1 \middle| O_{i,j,n} = 2\right) \geq p \text{ and } \mathbb{P}\left(O_{i,j+1,n} = 2 \middle| O_{i,j,n} = 1\right) \geq p. \tag{63}$$

Indeed, let l the (random) index such that $\tau^{(1)}_{i,l,n} = \tau^{O}_{i,j,n}$. Conditionally on $\left\{O_{i,j,n} = 1\right\}$, we know that $O_{i,j+1,n} = 2$ if $\Delta X^{(4)}_{[\tau^h_{i,n} + \tau^l_{i,j,n}, \cdot]}$ crosses g^+ or $-g^+$ before $\Delta X^{(3)}_{[\tau^h_{i,n} + \tau^O_{i,j,n}, \cdot]}$ crosses g^- or $-g^-$. Using (8) of (A2) and (51), we can easily bound away from 0 this probability, thus we deduce (63). Now, using (22) together with (63) and strong Markov property of Brownian motions, we deduce (62).

Third step : let $g = (d, u)$ such that $(g, g) \in \mathcal{G}$, $\sigma \in [\sigma^-, \sigma^+]$ and $\epsilon \leq \frac{g^-}{2}$. We define $\tau\left(g, \sigma, \epsilon\right) = \inf\{t > 0 : \sigma W_t = u(t) + \epsilon \text{ or } \sigma W_t = d(t) - \epsilon\}$, where W_t is a standard Brownian motion. We show that

$$\mathbb{E}\left[\left|\tau\left(g, \sigma, \epsilon\right) - \tau\left(g, \sigma, 0\right)\right|^l\right] \leq \gamma^{(l)}\left(\epsilon\right) \tag{64}$$

where $\gamma^{(l)}\left(\epsilon\right) \overset{\epsilon \to 0}{\to} 0$.

In order to show (64), let

$$\tau^1\left(g, \sigma, \epsilon\right) = \inf\{t > 0 : \sigma W_{t+\tau(g,\sigma,0)} = \min\left(u(\tau(g,\sigma,0)) + Kt + \epsilon, g^+\right)$$
$$\text{or } \sigma W_{t+\tau(g,\sigma,0)} = \max\left(d(\tau(g,\sigma,0)) - Kt - \epsilon, g^-\right)\}.$$

By (9) and (11) of (A3), we have $\tau\left(g, \sigma, \epsilon\right) - \tau\left(g, \sigma, 0\right) \leq \tau^1\left(g, \sigma, \epsilon\right)$. Conditionally on $\left\{\tau\left(g, \sigma, \epsilon\right)\right\}$, using strong Markov property of Brownian motions, we can show that $\mathbb{E}_{\tau(g,\sigma,\epsilon)}\left[\left|\tau^1\left(g, \sigma, \epsilon\right)\right|^l\right] \overset{\epsilon \to 0}{\to} 0$ using Theorem 2 in Potzelberger and Wang (2001) for instance.

Fourth step : let $k \in \{1, 2\}$. We show here that

$$\sum_{j \leq M_n} \mathbb{E}\left[\left|\tau^{(k)}_{i,j,n} - \tilde{\tau}^{(k)}_{i,j,n}\right|^l\right] = o^U_p\left(\alpha^{2l}_n\right). \tag{65}$$

The idea is to show that by recurrence in j, $\mathbb{E}\left[\left|\tau^{(k)}_{i,j,n} - \tilde{\tau}^{(k)}_{i,j,n}\right|^l\right]$ can be arbitrarily small when n grows. It is then a straightforward analysis exercise to use the localization in second step and choose a different sequence h if necessary, that will still be non-random increasing and following (53) and (54), so that the sum in (65) will be also arbitrarily small. Let's start with $j = 1$ and $k = 1$.

$$\mathbb{E}\left[\left|\tau^{(k)}_{i,1,n} - \tilde{\tau}^{(k)}_{i,1,n}\right|^l\right] = \mathbb{E}\left[\left|\tau^{(k)}_{i,1,n} - \tilde{\tau}^{(k)}_{i,1,n}\right|^l \mathbf{1}_{E_{i,n}}\right] + \mathbb{E}\left[\left|\tau^{(k)}_{i,1,n} - \tilde{\tau}^{(k)}_{i,1,n}\right|^l \mathbf{1}_{E^C_{i,n}}\right],$$

where $E_{i,n} = E^{(1)}_{i,n} \cap E^{(2)}_{i,n}$ with

$$E^{(1)}_{i,n} = \left\{ \sup_{s \in [\tau^h_{i,n}, \tau^h_{i,n} + \tau^{(1)}_{i,1,n} \vee \tilde{\tau}^{(1)}_{i,1,n}]} \left|\Delta X^{(1)}_{[\tau^h_{i,n}, s]} - \Delta \tilde{X}^{(1)}_{[\tau^h_{i,n}, s]}\right| < \eta_{1,n} \right\},$$

$$E^{(2)}_{i,n} = \left\{ \sup_{s \in [\tau^h_{i,n}, \tau^h_{i,n} + \tau^{(1)}_{i,1,n} \vee \tilde{\tau}^{(1)}_{i,1,n}]} \left\|g^{(1)}_s - g^{(1)}_{\tau^h_{i,n}}\right\|_\infty < \eta_{1,n} \right\},$$

$\eta_{1,n} = q_n \alpha_n$, $q_n = \max\left(\alpha_n^{d-1/2}, z_n^{1/2}\right)$ and $z_n = \sup_{1 \le u,v \le 4} \left(\mathbb{E}\left[\left(S\left(\sigma^{u,v}, s^h_n \vee \tilde{s}^h_n\right)\right)^2\right]\right)^{1/2}$. By (58) and (64),

$$\mathbb{E}\left[\left|\tau^{(k)}_{i,1,n} - \tilde{\tau}^{(k)}_{i,1,n}\right|^l \mathbf{1}_{E_{i,n}}\right] \le C\alpha_n^{2l}\left(\gamma^{(l)}\left(2q_n\right) + \gamma^{(l)}\left(-2q_n\right)\right).$$

Using Cauchy-Schwarz inequality and Lemma 7,

$$\mathbb{E}\left[\left|\tau^{(k)}_{i,1,n} - \tilde{\tau}^{(k)}_{i,1,n}\right|^l \mathbf{1}_{E^C_{i,n}}\right] \le C\alpha_n^{2l}\mathbb{P}\left(E^C_{i,n}\right)^{1/2} \le C\alpha_n^{2l}\left(\mathbb{P}\left(\left(E^{(1)}_{i,n}\right)^C\right) + \mathbb{P}\left(\left(E^{(2)}_{i,n}\right)^C\right)\right)^{1/2}.$$

On the one hand,

$$\begin{aligned}
\mathbb{P}\left(\left(E^{(1)}_{i,n}\right)^C\right) &\le (\eta_{1,n})^{-1}\,\mathbb{E}\left[\sup_{s \in [\tau^h_{i,n}, \tau^h_{i,n} + \tau^{(1)}_{i,1,n} \vee \tilde{\tau}^{(1)}_{i,1,n}]} \left|\Delta X^{(1)}_{[\tau^h_{i,n}, s]} - \Delta \tilde{X}^{(1)}_{[\tau^h_{i,n}, s]}\right|\right] \\
&\le C\left(\eta_{1,n}\right)^{-1} \max_{1 \le u,v \le 4} \mathbb{E}\left[\left(\int_{\tau^h_{i,n}}^{\tau^h_{i,n} + \tau^{(1)}_{i,1,n} \vee \tilde{\tau}^{(1)}_{i,1,n}} \left(\sigma^{u,v}_s - \sigma^{u,v}_{\tau^h_{i,n}}\right)^2 ds\right)^{1/2}\right] \\
&\le C\left(\eta_{1,n}\right)^{-1} \max_{1 \le u,v \le 4} \mathbb{E}\left[\left(\left(\tau^{(1)}_{i,1,n} \vee \tilde{\tau}^{(1)}_{i,1,n}\right) S\left(\sigma^{u,v}, s^h_n \vee \tilde{s}^h_n\right)^2\right)^{1/2}\right] \\
&\le C\left(\eta_{1,n}\right)^{-1}\left(\mathbb{E}\left[\tau^{(1)}_{i,1,n} \vee \tilde{\tau}^{(1)}_{i,1,n}\right]\right)^{1/2} z_n \\
&\le C z_n^{1/2}.
\end{aligned}$$

where we used Markov inequality in the first inequality, conditional Burkholder-Davis-Gundy inequality in the second inequality, Cauchy-Schwarz inequality in the fourth inequality, Lemma 7 in the last inequality. On the other hand,

$$\begin{aligned}\mathbb{P}\left(\left(E_{i,n}^{(2)}\right)^{C}\right) &\leq (\eta_{1,n})^{-1}\,\mathbb{E}\left[\sup_{s\in[\tau_{i,n}^{h},\tau_{i,n}^{h}+\tau_{i,1,n}^{(1)}\vee\tilde{\tau}_{i,1,n}^{(1)}]}\left\|g_s^{(1)}-g_{\tau_{i,n}^{h}}^{(1)}\right\|_\infty\right]\\ &\leq C\,(\eta_{1,n})^{-1}\,\mathbb{E}\left[\left(\tau_{i,1,n}^{(1)}\vee\tilde{\tau}_{i,1,n}^{(1)}\right)^{d}\right]\\ &\leq C\alpha_n^{d-1/2}.\end{aligned}$$

where we used Markov inequality in the first inequality, (12) of (A3) in the second inequality, Lemma 7 in the last inequality. In summary, we have

$$\mathbb{E}\left[\left|\tau_{i,j,n}^{(k)}-\tilde{\tau}_{i,j,n}^{(k)}\right|^{l}\right]\leq C\alpha_n^{2l}\left(\gamma^{(l)}\left(2q_n\right)+\gamma^{(l)}\left(-2q_n\right)+z_n^{1/2}+\alpha^{d-1/2}\right).$$

which we can make arbitrarily small, because $z_n\to 0$ by first step together with Lemma 6 and the continuity of σ (A1). The case with $k=2$ is very similar. Finally, for $j>1$, the same kind of computation techniques, using in addition (11) of (A3), will work.

Fifth step : Prove that uniformly (in i)

$$\mathbb{P}\left(\forall j\leq M_n, O_{i,j,n}=\tilde{O}_{i,j,n}\right)\to 1. \tag{66}$$

To show (66), let $j\leq M_n$. We define the (random) index v such that $\tau_{i,v,n}^{O}=\tau_{i,j,n}^{(k)}$. Modifying suitably h if needed, there exists (using fourth step) a sequence (ϵ_n) such that

$$\mathbb{P}\left(\left|\tau_{i,j,n}^{(k)}-\tilde{\tau}_{i,j,n}^{(k)}\right|\leq\alpha_n^2\epsilon_n\right)\to 1, \tag{67}$$

$$\mathbb{P}\left(\left|\tau_{i,v+1,n}^{O}-\tau_{i,v,n}^{O}\right|\leq\alpha_n^2\epsilon_n\right)\to 0. \tag{68}$$

Using (67) and (68), we can verify (66) by recurrence.

Sixth step : We prove here (59) and (60). Using Lemma 7 and (66) we obtain

$$\mathbb{E}\left[\left|\Delta\tau_{i,j,n}^{1C}-\Delta\tilde{\tau}_{i,j,n}^{1C}\right|^{l}\right]=\mathbb{E}\left[\left|\Delta\tau_{i,j,n}^{1C}-\Delta\tilde{\tau}_{i,j,n}^{1C}\right|^{l}\mathbf{1}_{\{\forall j\leq M_n,O_{i,j,n}=\tilde{O}_{i,j,n}\}}\right]+o_p^U\left(\alpha_n^{2l}\right).$$

The first term on the right part of the inequality can be bounded by

$$C\Bigg(\mathbb{E}\left[\left|\tau^{1C}_{i,j,n}-\tilde{\tau}^{1C}_{i,j,n}\right|^{l}\mathbf{1}_{\{\forall j\leq M_n, O_{i,j,n}=\tilde{O}_{i,j,n}\}}\right]$$

$$+\mathbb{E}\left[\left|\tau^{1C}_{i,j-1,n}-\tilde{\tau}^{1C}_{i,j-1,n}\right|^{l}\mathbf{1}_{\{\forall j\leq M_n, O_{i,j,n}=\tilde{O}_{i,j,n}\}}\right]\Bigg).$$

Both terms can be treated with the same trick. Using the second step and Lemma 7, the first term is equal to

$$\sum_{v\leq M_n}\mathbb{E}\left[\left|\tau^{1C}_{i,j,n}-\tilde{\tau}^{1C}_{i,j,n}\right|^{l}\mathbf{1}_{\{\forall j\leq M_n, O_{i,j,n}=\tilde{O}_{i,j,n}\}}\mathbf{1}_{\{\tau^{1C}_{i,j,n}=\tau^{(1)}_{i,v,n}\}}\right]+o_p^U\left(\alpha_n^{2l}\right).$$

The sum is obviously bounded by

$$\sum_{v\leq M_n}\mathbb{E}\left[\left|\tau^{1C}_{i,j,n}-\tilde{\tau}^{1C}_{i,j,n}\right|^{l}\right].$$

and using (65), we prove (59). We can deduce (60) with the same kind of computations.

□

Let M^n the interpolated normalized error, i.e.

$$M^n_t=\alpha_n^{-1}\left(\sum_{i\geq 1}\Delta X^{(1)}_{[\tau^{1C}_{i-1,n}\wedge t,\tau^{1C}_{i,n}\wedge t]}\Delta X^{(2)}_{[\tau^{1C,-}_{i-1,n}\wedge t,\tau^{1C,+}_{i,n}\wedge t]}-\int_0^t\sigma^{(1)}_s\sigma^{(2)}_s\rho^{1,2}_s ds\right).$$

M^n_t corresponds exactly to the normalized error of the Hayashi-Yoshida estimator if we observe the price of both assets at time t. We recall the definition of

$$N_{i,n}=\Delta X^{(1)}_{\tau^{1C}_{i,n}}\Delta X^{(2)}_{\tau^{1C,-,+}_{i,n}}-\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\sigma^{(1)}_s\sigma^{(2)}_s\rho^{1,2}_s ds.$$

Lemma 12. *We have*

$$\sum_{i\in A_n}\mathbb{E}_{\tau^h_{i-1,n}}\left[\left(\Delta M^n_{\tau^h_{i,n}}\right)^2\right]$$

$$=\alpha_n^{-2}\sum_{i\in A_n}\mathbb{E}_{\tau^h_{i-1,n}}\left[\sum_{u=2}^{h_n}\left(N_{(i-1)h_n+u}\right)^2+2N_{(i-1)h_n+u}N_{(i-1)h_n+u+1}\right]+o_p(1).$$

Proof. We obtain this equality noting that $(N_{i,n})_{n\geq 0}$ are centered and 1-correlated, and that the terms left converge to 0 in probability. $\square$

We introduce the observation time at the start of a block, where "s" stands for "start"

$$\tau^s_{i,n} = \sup\{\tau^h_{j,n} \text{ s.t. } \tau^h_{j,n} < \tau^{1C}_{i,n}\}.$$

Lemma 13. *We have*

$$\alpha_n^{-2} \sum_{i\in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\sum_{u=2}^{h_n} \left(N_{(i-1)h_n+u}\right)^2 + 2N_{(i-1)h_n+u}N_{(i-1)h_n+u+1} \right]$$

$$= \alpha_n^2 \sum_{i\in A_n} \sum_{j=0}^{h_n-2} \int_{\mathbb{R}^2} \psi^{AV}\left(\sigma_{\tau^h_{i-1,n}}, g_{\tau^h_{i-1,n}}, \alpha_n^{-1}x, \alpha_n^{-2}v\right) d\tilde{\pi}_{i-1,j,n}(x,v) + o_p(1).$$

Proof. First step : approximating with holding volatility constant. Set

$$\tilde{N}_{i,n} = \left(\sigma_{\tau^s_{i-1,n}} \Delta W_{\tau^{1C}_{i,n}}\right)^{(1)} \left(\sigma_{\tau^s_{i-1,n}} \Delta W_{\tau^{1C,-,+}_{i,n}}\right)^{(2)} - \int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}} \zeta^{1,2}_{\tau^s_{i-1,n}} ds$$

where $A^{(i)}$ is the i-th component of the vector A. We want to show that :

$$\alpha_n^{-2} \sum_{i\in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\sum_{u=2}^{h_n} \left(N_{(i-1)h_n+u}\right)^2 + 2N_{(i-1)h_n+u}N_{(i-1)h_n+u+1} \right]$$

$$= \alpha_n^{-2} \sum_{i\in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\sum_{u=2}^{h_n} \left(\tilde{N}_{(i-1)h_n+u}\right)^2 + 2\tilde{N}_{(i-1)h_n+u}\tilde{N}_{(i-1)h_n+u+1} \right] + o_p(1).$$

Noting $F_{i,n} = (N_{i,n})^2 + 2N_{i,n}N_{i+1,n}$ and $\tilde{F}_{i,n} = \left(\tilde{N}_{i,n}\right)^2 + 2\tilde{N}_{i,n}\tilde{N}_{i+1,n}$, it is sufficient to show that

$$\alpha_n^{-2} \sum_{i\geq 1} \mathbb{E}_{\tau^s_{i-1,n}} \left[\left| F_{i,n} - \tilde{F}_{i,n} \right| \mathbf{1}_{\{\tau^s_{i-1,n}<t\}} \right] \xrightarrow{\mathbb{P}} 0,$$

that we can rewrite as $\alpha_n^{-2} \sum_{i\geq 1}^{N^{(1)}_{t,n}} \mathbb{E}_{\tau^s_{i-1,n}} \left[\left| F_{i,n} - \tilde{F}_{i,n} \right| \mathbf{1}_{\{\tau^s_{i-1,n}<t\}} \right] \xrightarrow{\mathbb{P}} 0$. Using Lemma 9, it is sufficient to show that $\forall u > 0$:

$$\alpha_n^{-2} \sum_{i=1}^{u\alpha_n^{-2}} \mathbb{E}_{\tau^s_{i-1,n}} \left[\left| F_{i,n} - \tilde{F}_{i,n} \right| \mathbf{1}_{\{\tau^s_{i-1,n}<t\}} \right] \xrightarrow{\mathbb{P}} 0.$$

Thus, it is sufficient to show the convergence $\mathbf{L}^1$ of this quantity, i.e. that

$$\alpha_n^{-2}\sum_{i=1}^{u\alpha_n^{-2}} \mathbb{E}\left[\left|F_{i,n}-\tilde{F}_{i,n}\right|\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\right]\to 0.$$

We have that

$$\left|F_{i,n}-\tilde{F}_{i,n}\right| \leq B^{(1)}_{i,n}+2B^{(2)}_{i,n},$$

where $B^{(1)}_{i,n}=\left|N^2_{i,n}-\tilde{N}^2_{i,n}\right|$ and $B^{(2)}_{i,n}=\left|N_{i-1,n}N_{i,n}-\tilde{N}_{i-1,n}\tilde{N}_{i,n}\right|$. We have that

$$B^{(1)}_{i,n}\leq C^{(1)}_{i,n}+C^{(2)}_{i,n}+C^{(3)}_{i,n},$$

where

$$\begin{aligned}
C^{(1)}_{i,n} &= \left|\left(\Delta X^{(1)}_{\tau^{1C}_{i,n}}\Delta X^{(2)}_{\tau^{1C,-,+}_{i,n}}\right)^2-\left(\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C}_{i,n}}\right)^{(1)}\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C,-,+}_{i,n}}\right)^{(2)}\right)^2\right|,\\
C^{(2)}_{i,n} &= \left|\left(\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\zeta^{1,2}_s ds\right)^2-\left(\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\zeta^{1,2}_{\tau^s_{i-1,n}} ds\right)^2\right|,
\end{aligned}$$

$$\begin{aligned}
C^{(3)}_{i,n} &= 2\Bigg|\Delta X^{(1)}_{\tau^{1C}_{i,n}}\Delta X^{(2)}_{\tau^{1C,-,+}_{i,n}}\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\zeta^{1,2}_s ds\\
&\quad -\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C}_{i,n}}\right)^{(1)}\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C,-,+}_{i,n}}\right)^{(2)}\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\zeta^{1,2}_{\tau^s_{i-1,n}} ds\Bigg|.
\end{aligned}$$

Let's show that $\alpha_n^{-2}\sum_{i=1}^{u\alpha_n^{-2}}\mathbb{E}\left[C^{(1)}_{i,n}\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\right]\to 0$. We can write it as $C^{(1)}_{i,n}\leq D^{(1)}_{i,n}+D^{(2)}_{i,n}$, where

$$\begin{aligned}
D^{(1)}_{i,n} &= \left|\left(\Delta X^{(1)}_{\tau^{1C}_{i,n}}\Delta X^{(2)}_{\tau^{1C,-,+}_{i,n}}\right)^2\left(\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C}_{i,n}}\right)^{(1)}\Delta X^{(2)}_{\tau^{1C,-,+}_{i,n}}\right)^2\right|,\\
D^{(2)}_{i,n} &= \Bigg|\left(\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C}_{i,n}}\right)^{(1)}\Delta X^{(2)}_{\tau^{1C,-,+}_{i,n}}\right)^2-\\
&\quad -\left(\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C}_{i,n}}\right)^{(1)}\left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C,-,+}_{i,n}}\right)^{(2)}\right)^2\Bigg|.
\end{aligned}$$

We want to show that $\alpha_n^{-2} \sum_{i=1}^{u\alpha_n^{-2}} \mathbb{E}\left[D_{i,n}^{(1)} \mathbf{1}_{\{\tau_{i-1,n}^s < t\}}\right] \to 0$. We define :

$$\begin{aligned} E_{i,n}^{(1)} &= \Delta X_{\tau_{i,n}^{1C}}^{(1)} \Delta X_{\tau_{i,n}^{1C,-,+}}^{(2)}, \\ E_{i,n}^{(2)} &= \left(\sigma_{\tau_{i-1,n}^s} \Delta W_{\tau_{i,n}^{1C}}\right)^{(1)} \Delta X_{\tau_{i,n}^{1C,-,+}}^{(2)}. \end{aligned}$$

Using Cauchy-Schwarz inequality, we deduce :

$$\begin{aligned} \mathbb{E}\left[D_{i,n}^{(1)} \mathbf{1}_{\{\tau_{i-1,n}^s < t\}}\right] &= \mathbb{E}\left[\left(E_{i,n}^{(1)} + E_{i,n}^{(2)}\right)\left(E_{i,n}^{(1)} - E_{i,n}^{(2)}\right) \mathbf{1}_{\{\tau_{i-1,n}^s < t\}}\right] \\ &\leq \left(\mathbb{E}\left[\left(E_{i,n}^{(1)} + E_{i,n}^{(2)}\right)^2\right] \mathbb{E}\left[\left(E_{i,n}^{(1)} - E_{i,n}^{(2)}\right)^2 \mathbf{1}_{\{\tau_{i-1,n}^s < t\}}\right]\right)^{1/2}. \end{aligned}$$

Using Cauchy-Schwarz inequality together with Burkholder-Davis-Gundy inequality and Lemma 7, we obtain that :

$$\mathbb{E}\left[\left(E_{i,n}^{(1)} + E_{i,n}^{(2)}\right)^2\right] = O^U\left(\alpha_n^4\right).$$

where U stands for "uniformly in $1 \leq i \leq u\alpha_n^{-2}$". Another application of Cauchy-Schwarz inequality gives us

$$\mathbb{E}\left[\left(E_{i,n}^{(1)} - E_{i,n}^{(2)}\right)^2 \mathbf{1}_{\{\tau_{i-1,n}^s < t\}}\right]$$

$$\leq \left(\mathbb{E}\left[\left(\Delta X_{\tau_{i,n}^{1C}}^{(1)} - \left(\sigma_{\tau_{i-1,n}^s} \Delta W_{\tau_{i,n}^{1C}}\right)^{(1)}\right)^4 \mathbf{1}_{\{\tau_{i-1,n}^s < t\}}\right] \mathbb{E}\left[\left(\Delta X_{\tau_{i,n}^{1C,-,+}}^{(2)}\right)^4\right]\right)^{1/2}.$$

Using once again Cauchy-Schwarz inequality together with Burholder-Davis-Gundy inequality and Lemma 7, we obtain that :

$$\mathbb{E}\left[\left(\Delta X_{\tau_{i,n}^{1C,-,+}}^{(2)}\right)^4\right] = O^U\left(\alpha_n^4\right).$$

Similarly, we compute using conditional Burkholder-Davis-Gundy in first inequality, Cauchy-Schwarz in third inequality, Lemma 5, Lemma 6 and Lemma 7 together with the continuity of σ (A1) in last equality.

$$\mathbb{E}\left[\left(\Delta X_{\tau_{i,n}^{1C}}^{(1)} - \left(\sigma_{\tau_{i-1,n}^s} \Delta W_{\tau_{i,n}^{1C}}\right)^{(1)}\right)^4 \mathbf{1}_{\{\tau_{i-1,n}^s < t\}}\right]$$

$$
\begin{aligned}
&= \mathbb{E}\left[\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\mathbb{E}_{\tau^{1C}_{i-1,n}}\left[\left(\Delta X^{(1)}_{\tau^{1C}_{i,n}} - \left(\sigma_{\tau^s_{i-1,n}}\Delta W_{\tau^{1C}_{i,n}}\right)^{(1)}\right)^4\right]\right] \\
&= \mathbb{E}\left[\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\mathbb{E}_{\tau^{1C}_{i-1,n}}\left[\left(\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\left(\left(\sigma_s - \sigma_{\tau^s_{i-1,n}}\right)dW_s\right)^{(1)}\right)^4\right]\right] \\
&\leq C\sup_{1\leq j,l\leq 4}\mathbb{E}\left[\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\mathbb{E}_{\tau^{1C}_{i-1,n}}\left[\left(\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\left(\sigma^{j,l}_s - \sigma^{j,l}_{\tau^s_{i-1,n}}\right)^2 ds\right)^2\right]\right] \\
&= C\sup_{1\leq j,l\leq 4}\mathbb{E}\left[\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\left(\int_{\tau^{1C}_{i-1,n}}^{\tau^{1C}_{i,n}}\left(\sigma^{j,l}_s - \sigma^{j,l}_{\tau^s_{i-1,n}}\right)^2 ds\right)^2\right]
\end{aligned}
$$

$$
\begin{aligned}
&\leq C\sup_{1\leq j,l\leq 4}\mathbb{E}\left[\left(\Delta\tau^{1C}_{i,n}S\left(\sigma^{j,l},s^h_n\right)^2\right)^2\right] + o^U\left(\alpha_n^4\right) \\
&\leq C\left(\mathbb{E}\left[\left(\Delta\tau^{1C}_{i,n}\right)^4\right]\mathbb{E}\left[\sup_{1\leq j,l\leq 4}\left(S\left(\sigma^{j,l},s^h_n\right)\right)^8\right]\right)^{1/2} + o^U\left(\alpha_n^4\right) \\
&= O^U\left(\alpha_n^4\right).
\end{aligned}
$$

With the same kind of computations, we show that $\alpha_n^{-2}\sum_{i=1}^{u\alpha_n^{-2}}\mathbb{E}\left[D^{(2)}_{i,n}\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\right]\to 0$, and we also can show $\alpha_n^{-2}\sum_{i=1}^{u\alpha_n^{-2}}\mathbb{E}\left[C^{(2)}_{i,n}\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\right]\to 0$, $\alpha_n^{-2}\sum_{i=1}^{u\alpha_n^{-2}}\mathbb{E}\left[C^{(3)}_{i,n}\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\right]\to 0$ (thus we have also that $\alpha_n^{-2}\sum_{i=1}^{u\alpha_n^{-2}}\mathbb{E}\left[B^{(1)}_{i,n}\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\right]\to 0$) and

$$
\alpha_n^{-2}\sum_{i=1}^{u\alpha_n^{-2}}\mathbb{E}\left[B^{(2)}_{i,n}\mathbf{1}_{\{\tau^s_{i-1,n}<t\}}\right]\to 0.
$$

Second step : approximating using $\left(\tilde{\tau}_{i,j,n}\right)_{i,j,n\geq 0}$ instead of $\left(\tau_{i,n}\right)_{i,n\geq 0}$. We set

$$
\tilde{\tilde{N}}_{i,j,n} = \left(\sigma_{\tau^h_{i,n}}\Delta W_{\tilde{\tau}^{1C}_{i,j,n}}\right)^{(1)}\left(\sigma_{\tau^h_{i,n}}\Delta W_{\tilde{\tau}^{1C,-,+}_{i,j,n}}\right)^{(2)} - \int_{\tilde{\tau}^{1C}_{i,j-1,n}}^{\tilde{\tau}^{1C}_{i,j,n}}\zeta^{1,2}_{\tau^h_{i,n}}ds.
$$

We want to show that

$$
\alpha_n^{-2}\sum_{i\in A_n}\mathbb{E}_{\tau^h_{i-1,n}}\left[\sum_{u=2}^{h_n}\left(\tilde{N}_{(i-1)h_n+u}\right)^2 + 2\tilde{N}_{(i-1)h_n+u}\tilde{N}_{(i-1)h_n+u+1}\right]
$$

$$= \alpha_n^{-2} \sum_{i\in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\sum_{u=2}^{h_n} \left(\tilde{\tilde{N}}_{i-1,u,n}\right)^2 + 2\tilde{\tilde{N}}_{i-1,u,n}\tilde{\tilde{N}}_{i,u+1,n} \right] + o_p\left(1\right).$$

Using the same kind of computations as in the first step together with Lemma 11, we conclude.

Third step : express the result as a function of ψ^{AV}. Using Lemma 10 in last equality, we deduce for any integer u such that $2 \leq u \leq h_n$ that

$$\begin{aligned} & \mathbb{E}_{\tau^h_{i-1,n}} \left[\left(\tilde{\tilde{N}}_{i-1,u,n}\right)^2 + 2\tilde{\tilde{N}}_{i-1,u,n}\tilde{\tilde{N}}_{i-1,u+1,n} \right] \\ = \; & \int_{\mathbb{R}^2} \psi^{AV} \left(\sigma_{\tau^h_{i-1,n}}, \alpha_n g_{\tau^h_{i-1,n}}, x, v\right) d\tilde{\pi}_{i,u-2,n}\left(x, v\right) \\ = \; & \alpha_n^4 \int_{\mathbb{R}^2} \psi^{AV} \left(\sigma_{\tau^h_{i-1,n}}, g_{\tau^h_{i-1,n}}, \alpha_n^{-1} x, \alpha_n^{-2} v\right) d\tilde{\pi}_{i,u-2,n}\left(x, v\right). \end{aligned}$$

□

Lemma 14. *$\forall \sigma \in \mathcal{M}, g \in \mathcal{G}, \exists \pi\left(\sigma, g\right)$ distribution such that :*

$$\alpha_n^2 \sum_{i\in A_n} \sum_{j=0}^{h_n-2} \int_{\mathbb{R}^2} \psi^{AV} \left(\sigma_{\tau^h_{i-1,n}}, g_{\tau^h_{i-1,n}}, \alpha_n^{-1} x, \alpha_n^{-2} u\right) d\tilde{\pi}_{i-1,j,n}\left(x, u\right)$$

$$= \alpha_n^2 \sum_{i\in A_n} h_n \phi^{AV} \left(\sigma_{\tau^h_{i-1,n}}, g_{\tau^h_{i-1,n}}\right) + o_p(1).$$

Proof. We define the transition functions of the Markov chains $\left(\tilde{Z}_i\left(\sigma, g\right)\right)_{i\geq 0}$ defined in (33). For $(x, u) \in \mathcal{S}_g$, $B \in \mathcal{B}\left(\mathcal{S}_g\right)$ (borelians of $\mathcal{S}_g$)

$$P\left(\sigma, g\right)\left(\left(x, u\right), B\right) = \mathbb{P}\left(\tilde{Z}_1\left(\sigma, g\right) \in B \middle| \tilde{Z}_0\left(\sigma, g\right) = \left(x, u\right)\right).$$

First step : We prove that $\forall \sigma \in \mathcal{M}$, $\forall g \in \mathcal{G}$, the state space $\mathcal{S}_g$ is ν-small, i.e. there exists a non-trivial measure ν on $\mathcal{B}(\mathbb{R}^2)$ such that $\forall (x, u) \in \mathcal{S}_g, \forall B \in \mathcal{B}(\mathcal{S}_g)$, $P\left(\sigma, g\right)\left((x, u), B\right) \geq \nu\left(B\right)$. Let $B = [x_a, x_b] \times [u_a, u_b]$. We are choosing ν such that $\nu = 0$ outside $[-\frac{g^-}{4}, \frac{g^-}{4}] \times [3, 4]$. Thus, without loss of generality, we have that $[x_a, x_b] \times [u_a, u_b] \subset [-\frac{g^-}{4}, \frac{g^-}{4}] \times [3, 4]$. We want to show that $\exists c > 0$ such that uniformly

$$P\left(\sigma, g\right)\left(\left(x, u\right), B\right) \geq c\left(x_b - x_a\right)\left(u_b - u_a\right).$$

There are two useful ways to rewrite $(\tilde{X}^{(3)}, \tilde{X}^{(4)})$. The first one is :

$$\begin{aligned} \tilde{X}_t^{(3)} &:= \sigma^{(3)} \tilde{B}_t^{(3)}, && (69) \\ \tilde{X}_t^{(4)} &:= \rho^{3,4} \sigma^{(4)} \tilde{B}_t^{(3)} + \left(1 - \left(\rho^{3,4}\right)^2\right)^{1/2} \sigma^{(4)} \tilde{B}_t^{3,\perp}. && (70) \end{aligned}$$

where $\tilde{B}^{(3)}$ and $\tilde{B}^{3,\perp}$ are independent, $\rho^{3,4} \in [\rho_-^{3,4}, \rho_+^{3,4}]$ and $\max\left(-\rho_-^{3,4}, \rho_+^{3,4}\right) < 1$ (because $\sigma \in \mathcal{M}$),

$$\delta = \left(1 - \max\left(\left(\rho_-^{3,4}\right)^2, \left(\rho_+^{3,4}\right)^2\right)\right)^{1/2}. \tag{71}$$

The other way to rewrite it is :

$$\begin{aligned} \tilde{X}_t^{(4)} &:= \sigma^{(4)} \tilde{B}_t^{(4)}, && (72) \\ \tilde{X}_t^{(3)} &:= \rho^{3,4} \sigma^{(3)} \tilde{B}_t^{(4)} + \left(1 - \left(\rho^{3,4}\right)^2\right)^{1/2} \sigma^{(3)} \tilde{B}_t^{4,\perp}. && (73) \end{aligned}$$

where $\tilde{B}^{(4)}$ and $\tilde{B}^{4,\perp}$ are independent. For $(B_t)_{t \geq 0}$ a standard Brownian motion, $a < x < b$, we denote the exiting-zone time of the Brownian motion

$$\tau_x^{a,b} = \inf\{t > 0 \text{ s.t. } x + B_t = a \text{ or } x + B_t = b\}$$

and $p_1(x, a, b, t)$ the density of $\tau_x^{a,b}$. We also define $p_2(x, a, b, s, y)$ the distribution of $B_s + x$ conditioned on $\{\tau_x^{a,b} \geq s\}$. Finally, let $p_3(x, a, b, t)$ the distribution of $\tau_x^{a,b}$ conditioned on $\{B_{\tau_x^{a,b}} = b\}$. All the formulas can be found in Borodin and Salminen (2002). Consider the spaces $C_1 = C_3 = \{(x, a, b, t) \in \mathbb{R}^4 \text{ s.t. } a \leq x \leq b, t > 0\}$, $C_2 = \{(x, a, b, t, y) \in \mathbb{R}^5 \text{ s.t. } a \leq x \leq b \ , \ a < y < b \ , \ t > 0\}$. The functions p_i are continuous on C_i and positive. Thus, for all compact set $K_i \subset C_i$, we have

$$\inf_{k \in K_i} p_i(k) > 0. \tag{74}$$

We can bound below

$$P(\sigma, g)((x, u), B) \geq \mathbb{P}\left(E_0 \bigcap E_1 \bigcap E_2 \bigcap E_3 \bigcap E_4 \middle| \tilde{Z}_0 = (x, u)\right),$$

where

$$\begin{aligned}
E_0 &= \left\{\sup_{0\le s\le \tilde{\tau}_1^{(2)}}\left|\tilde{X}_s^{(3)}\right| < \frac{\epsilon\sigma^- \min(\sigma^-,1)}{15\sigma^+}\ ,\ \tilde{\tau}_1^{(2)}\le K\right\},\\
E_1 &= \left\{\sup_{\tilde{\tau}_1^{(2)}\le s\le K+1}\left|\tilde{X}_s^{(3)}\right| < \frac{\epsilon\sigma^-}{10\sigma^+}\ ,\ \sup_{\tilde{\tau}_1^{(2)}\le s\le K+1}\left|\Delta\tilde{B}^{3,\perp}_{[\tilde{\tau}_1^{(2)},s]}\right| < \frac{g^-\sigma^-}{4\left(\sigma^+\right)^2}\right\},\\
E_2 &= \left\{\sup_{K+1\le s\le \tilde{\tau}_2^{(2)}}\left|\tilde{X}_s^{(3)}\right| \le \frac{\epsilon}{5}\ ,\ \tilde{\tau}_2^{(2)}\in[K+2,K+3]\right\},\\
E_3 &= \left\{\forall s\in[\tilde{\tau}_2^{(2)},K+4]\ \tilde{X}_s^{(3)}\in[d_1(K),u_1(K)]\ ,\ \tilde{X}_{K+4}^{(3)}\in[u_1(K)-2\epsilon,u_1(K)-\epsilon]\right\}\\
&\qquad\bigcap\left\{\sup_{\tilde{\tau}_2^{(2)}\le s\le K+4}\left|\Delta\tilde{X}^{(4)}_{[\tilde{\tau}_2^{(2)},s]}\right| < \frac{g^-}{12}\right\},\\
E_4 &= \left\{\tilde{\tau}_1^{(1)}\in[u_a+\tilde{\tau}_2^{(2)},u_b+\tilde{\tau}_2^{(2)}]\ ,\ \inf_{K+4\le s\le\tilde{\tau}_1^{(1)}}\Delta\tilde{X}^{(3)}_{[K+4,s]} > -2\epsilon\right\}\\
&\qquad\bigcap\left\{\sup_{K+4\le s\le\tilde{\tau}_1^{(1)}}\left|\Delta\tilde{X}^{(4)}_{[\tilde{\tau}_2^{(2)},s]}\right| < g^-\ ,\ \Delta\tilde{X}^{(4)}_{[\tilde{\tau}_2^{(2)},\tilde{\tau}_1^{(1)}]}\in[x_a,x_b]\right\},
\end{aligned}$$

where $\epsilon=\frac{g^-\sigma^-}{24\sigma^+}$. Using extensively Bayes formula, we can rewrite

$$\mathbb{P}\left(E_0\bigcap E_1\bigcap E_2\bigcap E_3\bigcap E_4\bigcap\{\tilde{Z}_1\in B\}\middle|\tilde{Z}_0=(x,u)\right)=I\times II\times III\times IV\times V,$$

where $I=\mathbb{P}\left(E_0\middle|\{\tilde{Z}_0=(x,u)\}\right)$, $II=\mathbb{P}\left(E_1\middle|E_0\bigcap\{\tilde{Z}_0=(x,u)\}\right)$, and also $III=\mathbb{P}\left(E_2\middle|E_1\bigcap E_0\bigcap\{\tilde{Z}_0=(x,u)\}\right)$, $IV=\mathbb{P}\left(E_3\middle|E_2\bigcap E_1\bigcap E_0\bigcap\{\tilde{Z}_0=(x,u)\}\right)$ and $V=\mathbb{P}\left(E_4\middle|E_3\bigcap E_2\bigcap E_1\bigcap E_0\bigcap\{\tilde{Z}_0=(x,u)\}\right)$.

We prove that I is uniformly bounded away from 0. Using (52), (69), (70) and (71), we deduce that $E_0^{(1)}\bigcap E_0^{(2)}\subset E_0$ where

$$\begin{aligned}
E_0^{(1)} &= \left\{\sup_{0\le s\le K}\left|\tilde{B}_s^{(3)}\right| < \frac{\epsilon\sigma^-\min(\sigma^-,1)}{15\left(\sigma^+\right)^2}\right\},\\
E_0^{(2)} &= \left\{\sup_{0\le s\le K}\left|\frac{x}{\sigma^{(4)}\left(1-\left(\rho^{3,4}\right)^2\right)^{1/2}}+\tilde{B}_s^{3,\perp}\right| \ge \frac{g^+}{\delta\sigma^-}+\frac{\epsilon\sigma^-\min(\sigma^-,1)}{15\left(\sigma^+\right)^2}\right\}.
\end{aligned}$$

Conditionally on $\{\tilde{Z}_0=(x,u)\}$, $E_0^{(1)}$ and $E_0^{(2)}$ are independent. Thus, we deduce

$$I\ge\mathbb{P}\left(E_0^{(1)}\middle|\{\tilde{Z}_0=(x,u)\}\right)\mathbb{P}\left(E_0^{(2)}\middle|\{\tilde{Z}_0=(x,u)\}\right).$$

Using Markov property of Brownian motions, we obtain that the right part of the inequality is equal to

$$\left(1-\int_0^K p_1\left(0,-\frac{\epsilon\sigma^-\min(\sigma^-,1)}{15\left(\sigma^+\right)^2},\frac{\epsilon\sigma^-\min(\sigma^-,1)}{15\left(\sigma^+\right)^2},t\right)dt\right)\int_0^K p_1\left(y_0^{(1)},-y_0^{(2)},y_0^{(2)},t\right)dt,$$

where $y_0^{(1)}=\frac{x}{\sigma^{(4)}\left(1-(\rho^{3,4})^2\right)^{1/2}}$, $y_0^{(2)}=\frac{g^+}{\delta\sigma^-}+\frac{\epsilon\sigma^-\min(\sigma^-,1)}{15(\sigma^+)^2}$, which is uniformly (in x, σ and g) bounded away from 0 using (52) and (74).

We prove that II is uniformly bounded away from 0. Conditionally on $E_0\bigcap\{\tilde{Z}_0=(x,u)\}$, the two quantities of E_1 are independent. Thus, we bound below II (the same way we did for I) by

$$\left(1-\int_{\tilde{\tau}_1^{(2)}}^{K+1} p_1\left(\tilde{B}^{(3)}_{\tilde{\tau}_1^{(2)}},-\frac{\epsilon\sigma^-}{10\sigma^+\sigma^{(3)}},\frac{\epsilon\sigma^-}{10\sigma^+\sigma^{(3)}},t\right)dt\right)$$
$$\left(1-\int_{\tilde{\tau}_1^{(2)}}^{K+1} p_1\left(0,-\frac{g^-\sigma^-}{4\sigma^+\sigma^{(4)}},\frac{g^-\sigma^-}{4\sigma^+\sigma^{(4)}},t\right)dt\right),$$

which is uniformly bounded away from 0 using (52) together with (74).

We prove that III is uniformly bounded away from 0. Using (52), (69), (70) and (71), we deduce that $E_2^{(1)}\bigcap E_2^{(2)}\subset E_2$ where

$$\begin{aligned} E_2^{(1)} &= \Big\{\sup_{K+1\le s\le K+3}\left|\tilde{B}^{(3)}_s\right|\le\frac{\epsilon}{5\sigma^+}\Big\},\\ E_2^{(2)} &= \Big\{\sup_{K+1\le s\le K+2}\left|\Delta\tilde{B}^{3,\perp}_{[\tilde{\tau}_1^{(2)},s]}\right|<\frac{g^-}{2\sigma^+}\ ,\ \sup_{K+2\le s\le K+3}\left|\Delta\tilde{B}^{3,\perp}_{[\tilde{\tau}_1^{(2)},s]}\right|\ge\frac{g^+}{\delta\sigma^-}+\frac{\epsilon}{5\sigma^+\delta}\Big\}. \end{aligned}$$

Conditionally on $E_1\bigcap E_0\bigcap\{\tilde{Z}_0=(x,u)\}$, $E_2^{(1)}$ and $E_2^{(2)}$ are independent. Thus, we deduce

$$III\ge\mathbb{P}\left(E_2^{(1)}\middle|E_1\bigcap E_0\bigcap\{\tilde{Z}_0=(x,u)\}\right)\mathbb{P}\left(E_2^{(2)}\middle|E_1\bigcap E_0\bigcap\{\tilde{Z}_0=(x,u)\}\right).$$

Using Markov property of Brownian motions, we obtain that the right part of the inequality conditioned on $\{\tilde{B}^{(3)}_{K+1}\ ,\ \Delta\tilde{B}^{3,\perp}_{[\tilde{\tau}_1^{(2)},K+1]}\Big|E_1\bigcap E_0\bigcap\{\tilde{Z}_0=(x,u)\}\}$ is equal to

$$\left(1-\int_0^2 p_1\left(\tilde{B}^{(3)}_{K+1},-\frac{\epsilon}{5\sigma^+},\frac{\epsilon}{5\sigma^+},t\right)dt\right)\left(1-\int_0^1 p_1\left(\Delta\tilde{B}^{3,\perp}_{[\tilde{\tau}_1^{(2)},K+1]},-\frac{g^+}{2\sigma^+},\frac{g^+}{2\sigma^+},t\right)dt\right)$$

$$\times \int_{-\frac{g^-}{2\sigma^+}}^{\frac{g^-}{2\sigma^+}} \int_1^2 p_1\left(y, -\left(\frac{g^+}{\delta\sigma^-} + \frac{\epsilon}{5\sigma^+\delta}\right), \frac{g^+}{\delta\sigma^-} + \frac{\epsilon}{5\sigma^+\delta}, t\right) dt dq(y),$$

where q is the (conditional) distribution of $\Delta\tilde{B}^{3,\perp}_{[\tilde{\tau}_1^{(2)}, K+1]} + B_1$ conditioned on

$$\left\{\tau^{-\frac{g^-}{2\sigma^+}, \frac{g^-}{2\sigma^+}}_{\Delta\tilde{B}^{3,\perp}_{[\tilde{\tau}_1^{(2)}, K+1]}} \geq 1\right\}.$$

Using the definition of E_1 together with (52) and (74), we have III which is uniformly bounded away from 0.

We prove that IV is uniformly bounded away from 0. Using (72) and (73), we deduce that $E_3^{(1)} \bigcap E_3^{(2)} \subset E_3$ where

$$\begin{aligned} E_3^{(1)} &= \left\{\sup_{\tilde{\tau}_2^{(2)} \leq s \leq K+4} \left|\Delta\tilde{B}^{(4)}_{[\tilde{\tau}_2^{(2)}, s]}\right| < \frac{\epsilon\sigma^-}{5\sigma^+\sigma^{(4)}}\right\}, \\ E_3^{(2)} &= \left\{\forall s \in [\tilde{\tau}_2^{(2)}, K+4] \ \Delta\tilde{B}^{4,\perp}_{[\tilde{\tau}_2^{(2)}, s]} \in \left[y_3^{(1)}, y_3^{(2)}\right] , \ \Delta\tilde{B}^{4,\perp}_{[\tilde{\tau}_2^{(2)}, K+4]} \in \left[y_3^{(3)}, y_3^{(4)}\right]\right\}, \end{aligned}$$

with $y_3^{(1)} = \frac{d_1(K)+2\epsilon/5}{\sigma^{(4)}\left(1-(\rho^{3,4})^2\right)^{1/2}}$, $y_3^{(2)} = \frac{u_1(K)-2\epsilon/5}{\sigma^{(4)}\left(1-(\rho^{3,4})^2\right)^{1/2}}$, $y_3^{(3)} = \frac{u_1(K)-8\epsilon/5}{\sigma^{(4)}\left(1-(\rho^{3,4})^2\right)^{1/2}}$, as well as $y_3^{(4)} = \frac{u_1(K)-7\epsilon/5}{\sigma^{(4)}\left(1-(\rho^{3,4})^2\right)^{1/2}}$. Conditionally on $E_2 \bigcap E_1 \bigcap E_0 \bigcap \{\tilde{Z}_0 = (x, u)\}$, $E_3^{(1)}$ and $E_3^{(2)}$ are independent. Thus, we deduce

$$IV \geq \mathbb{P}\left(E_3^{(1)} \middle| E_2 \bigcap E_1 \bigcap E_0 \bigcap \{\tilde{Z}_0 = (x, u)\}\right)$$

$$\mathbb{P}\left(E_3^{(2)} \middle| E_2 \bigcap E_1 \bigcap E_0 \bigcap \{\tilde{Z}_0 = (x, u)\}\right).$$

Using Markov property of Brownian motions, we obtain that the right part of the inequality conditioned on $\{\tilde{\tau}_2^{(2)} \Big| E_2 \bigcap E_1 \bigcap E_0 \bigcap \{\tilde{Z}_0 = (x, u)\}\}$ is equal to

$$\left(1 - \int_0^{K+4-\tilde{\tau}_2^{(2)}} p_1\left(0, -\frac{\epsilon\sigma^-}{5\sigma^+\sigma^{(4)}}, \frac{\epsilon\sigma^-}{5\sigma^+\sigma^{(4)}}, t\right) dt\right)\left(1 - \int_0^{K+4-\tilde{\tau}_2^{(2)}} p_1\left(0, y_3^{(1)}, y_3^{(2)}, t\right) dt\right)$$

$$\times \int_{y_3^{(3)}}^{y_3^{(4)}} p_2\left(0, y_3^{(1)}, y_3^{(2)}, K+4-\tilde{\tau}_2^{(2)}, y\right) dy,$$

which is uniformly bounded away from 0 using (52), (71) and (74).

We prove that $V > c(x_b - x_a)(u_b - u_a)$. Using (69) and (70), we deduce that $E_4^{(1)} \bigcap E_4^{(2)} \subset E_4$ where

$$\begin{aligned} E_4^{(1)} &= \Big\{\tilde{\tau} \in [u_a + \tilde{\tau}_2^{(2)}, u_b + \tilde{\tau}_2^{(2)}] \ , \ \tilde{X}^{(3)}_{\tilde{\tau}} = u_1(K)\Big\}, \\ E_4^{(2)} &= \Big\{\sup_{K+4 \leq s \leq \tilde{\tau}} \left|\Delta \tilde{B}^{3,\perp}_{[K+4,s]}\right| < \frac{5g^-}{6\sigma^{(4)}\left(1 - (\rho^{3,4})^2\right)^{1/2}} \ , \ \Delta \tilde{B}^{3,\perp}_{[L+4,\tilde{\tau}]} \in [y_4^{(1)}, y_4^{(2)}]\Big\}, \end{aligned}$$

$\tilde{\tau} = \inf\{t > K+4 : \tilde{X}^{(3)}_t = u_1(K) \text{ or } \Delta \tilde{X}^{(3)}_{[K+4,t]} = -2\epsilon\}$,

$$y_4^{(1)} = \frac{x_a - \Delta \tilde{X}^{(4)}_{[\tilde{\tau}_2^{(2)}, K+4]} - \rho^{3,4}\sigma^{(4)}\left(\sigma^{(3)}\right)^{-1}\left(u_1(K) - \tilde{X}^{(3)}_{K+4}\right)}{\sigma^{(4)}\left(1 - (\rho^{3,4})^2\right)^{1/2}},$$

and $y_4^{(2)} = \frac{x_b - \Delta \tilde{X}^{(4)}_{[\tilde{\tau}_2^{(2)}, K+4]} - \rho^{3,4}\sigma^{(4)}\left(\sigma^{(3)}\right)^{-1}\left(u_1(K) - \tilde{X}^{(3)}_{K+4}\right)}{\sigma^{(4)}\left(1 - (\rho^{3,4})^2\right)^{1/2}}$. We have

$$V = \mathbb{P}\left(\tilde{X}^{(3)}_{\tilde{\tau}} = u_1(K)\right)$$

$$\times \mathbb{P}\left(E_4^{(1)} \bigcap E_4^{(2)} \middle| E_3 \bigcap E_2 \bigcap E_1 \bigcap E_0 \bigcap \{\tilde{Z}_0 = (x,u)\} \bigcap \{\tilde{X}^{(3)}_{\tilde{\tau}} = u_1(K)\}\right).$$

The first term on the right part of the equation is uniformly bounded away from 0 (Borodin and Salminen (2002)). Because $\tilde{\tau}$ is a function of $\tilde{X}^{(3)}$ and $\tilde{B}^{3,\perp}$ is independent with $\tilde{X}^{(3)}$, $\tilde{\tau}$ and $\tilde{B}^{3,\perp}$ are independent. Thus the second term on the right conditioned on

$$\{y_4^{(1)}, y_4^{(2)}, X^{(3)}_{K+4}, \tilde{\tau}_2^{(2)} \Big| E_3 \bigcap E_2 \bigcap E_1 \bigcap E_0 \bigcap \{\tilde{Z}_0 = (x,u)\}\}$$

can be expressed as :

$$\int_{u_a + \tilde{\tau}_2^{(2)} - (K+4)}^{u_b + \tilde{\tau}_2^{(2)} - (K+4)} \int_{y_4^{(1)}}^{y_4^{(2)}} p_3\left(\frac{X^{(3)}_{K+4}}{\sigma^{(3)}}, \frac{X^{(3)}_{K+4} - 2\epsilon}{\sigma^{(3)}}, \frac{u_1(K)}{\sigma^{(3)}}, t\right) p_2\left(0, -\frac{5g^-}{y_4^{(3)}}, \frac{5g^-}{y_4^{(3)}}, t, y\right) dtdy,$$

where $y_4^{(3)} = 6\sigma^{(4)}\left(1 - (\rho^{3,4})^2\right)^{1/2}$. We have that $y_4^{(1)}$ and $y_4^{(2)}$ are dominated by $\frac{3g^-}{4\sigma^{(4)}\left(1 - (\rho^{3,4})^2\right)^{1/2}}$. Using this together with (52), (71) and (74), we deduce that $V \geq c(x_b - x_a)(u_b - u_a)$.

Second step : We prove that $\left\|\psi^{AV}\right\|_{\infty} := \sup_{\sigma\in\mathcal{M},g\in\mathcal{G},(x,u)\in\mathcal{S}_g}\left|\psi^{AV}\left(\sigma,g,x,u\right)\right| < \infty$. To show this, we bound the term as

$$\mathbb{E}\left[\left(\Delta\tilde{X}^{(1)}_{\tilde{\tau}_2^{1C}}\Delta\tilde{X}^{(2)}_{\tilde{\tau}_2^{1C,-,+}} - \tilde{\zeta}^{1,2}\Delta\tilde{\tau}_2^{1C}\right)^2\right] \leq 2\mathbb{E}\left[\left(\Delta\tilde{X}^{(1)}_{\tilde{\tau}_2^{1C}}\Delta\tilde{X}^{(2)}_{\tilde{\tau}_2^{1C,-,+}}\right)^2 + \left(\tilde{\zeta}^{1,2}\Delta\tilde{\tau}_2^{1C}\right)^2\right].$$

The second term in the right hand-side of the inequality is uniformly bounded using (52) and Lemma 7. Using successively Cauchy-Schwarz and Burholder-Davis-Gundy inequality, (52) and Lemma 7, we can also bound uniformly the first term. The other term of (29) can be bounded in the same way.

Third step : Define $q = (\sigma, g, x, u)$ and

$$\mathcal{Q} = \left\{(\sigma, g, x, u) \text{ s.t. } \sigma \in \mathcal{M}, g \in \mathcal{G}, (x, u) \in \mathcal{S}_g\right\}.$$

Prove that $\forall q \in \mathcal{Q}$, there exists a measure $\tilde{\pi}\left(\sigma, g\right)$ such that

$$\sup_{q\in\mathcal{Q}}\left|\sum_{l=0}^{n-1}\int_{\mathbb{R}^2}\psi^{AV}\left(\sigma,g,y,v\right)d\tilde{\pi}_l\left(\sigma,g,x,u\right)\left(y,v\right) - n\int_{\mathbb{R}^2}\psi^{AV}\left(\sigma,g,y,v\right)d\tilde{\pi}\left(\sigma,g\right)\left(y,v\right)\right|$$
$$= no_p(1).$$

To show this, we use first step together with $Th.16.0.2$ (v) (Meyn and Tweedie (2009)). We obtain that there exists $\tilde{\pi}\left(\sigma, g\right)$ where

$$\left\|P^n\left(\sigma,g\right)\left(\left(x,u\right),.\right) - \tilde{\pi}\left(\sigma,g\right)\right\|_{TV} \leq 2r^n$$

and $r = 1 - \nu\left(\mathbb{R}^2\right)$. Thus, we deduce :

$$\left|\int_{\mathbb{R}^2}\psi^{AV}\left(\sigma,g,y,v\right)d\tilde{\pi}_l\left(\sigma,g,x,u\right)\left(y,v\right) - \int_{\mathbb{R}^2}\psi^{AV}\left(\sigma,g,y,v\right)d\tilde{\pi}\left(\sigma,g\right)\left(y,v\right)\right|$$

$$\leq \left\|\psi^{AV}\right\|_{\infty}\left\|\tilde{\pi}_l\left(\sigma,g,x,u\right) - \tilde{\pi}\left(\sigma,g\right)\right\|_{TV} \leq 2\left\|\psi^{AV}\right\|_{\infty} r^l. \tag{75}$$

We want to show that $\forall\epsilon > 0$, $\exists N > 0$ such that $\forall n \geq N$:

$$\left|\sum_{l=0}^{n-1}\int_{\mathbb{R}^2}\psi^{AV}\left(\sigma,g,y,v\right)d\tilde{\pi}_l\left(\sigma,g,x,u\right)\left(y,v\right) - n\int_{\mathbb{R}^2}\psi^{AV}\left(\sigma,g,y,v\right)d\tilde{\pi}\left(\sigma,g\right)\left(y,v\right)\right|$$

$$< \epsilon n. \tag{76}$$

The rest is a straightforward analysis exercise. Let $\epsilon > 0$. $\exists N_1 > 0$ such that $r^{N_1} < \frac{\epsilon}{2}$. Choosing $N > 8N_1\epsilon^{-1}\|\psi^{AV}\|_\infty^{-1}$, we first use the triangular inequality, and then split the sum of the left part of (76) in two parts, one up to N_1 and the other one up to N. We use (75) in the second part to obtain (76).

Fourth step : Proving the Lemma. Let $w > 0$. From Lemma 9, we just have to show that

$$\alpha_n^2 \sum_{i=1}^{\llcorner w\alpha_n^{-2}h(n)^{-1}\lrcorner} \left| \sum_{j=0}^{h_n-2} \int_{\mathbb{R}^2} \psi^{AV}\left(\sigma_{\tau_{i-1,n}^h}, g_{\tau_{i-1,n}^h}, \alpha_n^{-1}y, \alpha_n^{-2}v\right) d\tilde{\pi}_{i-1,j,n}(y,v) \right.$$
$$\left. - h_n\phi^{AV}\left(\sigma_{\tau_{i-1,n}^h}, g_{\tau_{i-1,n}^h}\right) \right|$$

tends to 0 in probability. Using third step together with standard results on regular conditional distributions (see for instance Section 4.3 (pp. $77-80$) in Breiman (1992)), we prove the lemma.

□

Lemma 15. *We have*

$$\alpha_n^2 \sum_{i\in A_n} \mathbb{E}_{\tau_{i-1,n}^h}\left[\left(\sigma^{(1)}_{\tau_{i-1,n}^h}\right)^2 \left(\sigma^{(2)}_{\tau_{i-1,n}^h}\right)^2 h_n\phi^{AV}\left(\sigma_{\tau_{i-1,n}^h}, g_{\tau_{i-1,n}^h}\right)\Delta\tau_{i,n}^h\left(\mathbb{E}_{\tau_{i-1}^h}\left[\Delta\tau_{i,n}^h\right]\right)^{-1}\right]$$
$$= \sum_{i\in A_n} \mathbb{E}_{\tau_{i-1,n}^h}\left[\phi^{AV}\left(\sigma_{\tau_{i-1,n}^h}, g_{\tau_{i-1,n}^h}\right)\Delta\tau_{i,n}^h\left(\phi^{\tau}_{\tau_{i-1,n}^h}\right)^{-1}\right] + o_p(1).$$

Proof. First step : Defining

$$\begin{cases} u_{i,n} & := & \sum_{j=0}^{h_n-2}\int_X \psi^{\tau}\left(\sigma_{\tau_{i-1,n}^h}, g_{\tau_{i-1,n}^h}, x, u\right) d\tilde{\pi}_{i-1,j,n}(x,u), \\ A_0 & := & \alpha_n^2\sum_{i\in A_n}\mathbb{E}_{\tau_{i-1,n}^h}\left[h_n\phi^{AV}\left(\sigma_{\tau_{i-1,n}^h}, g_{\tau_{i-1,n}^h}\right)\Delta\tau_{i,n}^h\left(\mathbb{E}_{\tau_{i-1}^h}\left[\Delta\tau_{i,n}^h\right]\right)^{-1}\right], \\ A_1 & := & \alpha_n^2\sum_{i\in A_n}\mathbb{E}_{\tau_{i-1,n}^h}\left[h_n\phi^{AV}\left(\sigma_{\tau_{i-1,n}^h}, g_{\tau_{i-1,n}^h}\right)\Delta\tau_{i,n}^h\left(u_{i,n}\right)^{-1}\right]. \end{cases}$$

we have that $A_0 = A_1 + o_p(1)$. To show this, in light of Lemma 11, we have that

$$\left|\mathbb{E}_{\tau_{i-1,n}^h}\left[\Delta\tau_{i,n}^h\right] - u_{i,n}\right| \leq h(n)\, C_n,$$

where C_n tends to 0 in probability. From this, we can easily show that $A_0 = A_1 + o_p(1)$.

Second step : We have that

$$A_1 = \sum_{i \in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\phi^{AV} \left(\sigma_{\tau^h_{i-1,n}}, g_{\tau^h_{i-1,n}} \right) \Delta \tau^h_{i,n} \left(\phi^{\tau}_{\tau^h_{i,n}} \right)^{-1} \right] + o_p(1).$$

To prove it, we can mimic the proof of Lemma 14, together with Lemma 11. □

8.3 Computation of the limits of $\langle M^n \rangle_t$, $\langle M^n, X^{(1)} \rangle_t$ and $\langle M^n, X^{(2)} \rangle_t$

$$\begin{aligned}
\langle M^n \rangle_t &= \sum_{i \in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\left(\Delta M^n_{\tau^h_{i,n}} \right)^2 \right] + o_p(1) \\
&= \alpha_n^{-2} \sum_{i \in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\sum_{u=2}^{h_n} \left(N_{(i-1)h_n+u} \right)^2 + 2 N_{(i-1)h_n+u} N_{(i-1)h_n+u+1} \right] + o_p(1) \\
&= \alpha_n^2 \sum_{i \in A_n} \sum_{j=0}^{h_n-2} \int_{\mathbb{R}^2} \psi^{AV} \left(\sigma_{\tau^h_{i-1,n}}, g_{\tau^h_{i-1,n}}, \alpha_n^{-1} x, \alpha_n^{-2} u \right) d\tilde{\pi}_{i-1,j,n}(x,u) + o_p(1),
\end{aligned}$$

where we used Lemma 2.2.11 of Jacod and Protter (2012) in first equality, Lemma 12 in second equality, Lemma 13 in third equality.

We deduce (using Lemma 14 in first equality and Lemma 15 in third equality)

$$\begin{aligned}
\langle M^n \rangle_t &= \alpha_n^2 \sum_{i \in A_n} h_n \phi^{AV}_{\tau^h_{i-1,n}} + o_p(1) \\
&= \alpha_n^2 \sum_{i \in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[h_n \phi^{AV}_{\tau^h_{i-1,n}} \Delta \tau^h_{i,n} \left(\mathbb{E}_{\tau^h_{i-1}} \left[\Delta \tau^h_{i,n} \right] \right)^{-1} \right] + o_p(1) \\
&= \sum_{i \in A_n} \mathbb{E}_{\tau^h_{i-1,n}} \left[\phi^{AV}_{\tau^h_{i-1,n}} \Delta \tau^h_{i,n} \left(\phi^{\tau}_{\tau^h_{i,n}} \right)^{-1} \right] + o_p(1).
\end{aligned}$$

Using Lemma 2.2.11 of Jacod and Protter (2012) again, we deduce

$$\langle M^n \rangle_t = \sum_{i \in A_n} \phi^{AV}_{\tau^h_{i-1,n}} \Delta \tau^h_{i,n} \left(\phi^{\tau}_{\tau^h_{i,n}} \right)^{-1} + o_p(1).$$

Using Lemma 5 together with Prop. $I.4.44$ (page 51) in Jacod and Shiryaev (2003), we obtain

$$\langle M^n \rangle_t \to \int_0^t \phi_s^{AV} \left(\phi_s^\tau\right)^{-1} ds. \tag{77}$$

Using the same approximations and computations, we also compute

$$\begin{aligned} \langle M^n, X^{(1)} \rangle_t &\to \int_0^t \phi_s^{AC1} \left(\phi_s^\tau\right)^{-1} ds, && (78) \\ \langle M^n, X^{(2)} \rangle_t &\to \int_0^t \phi_s^{AC2} \left(\phi_s^\tau\right)^{-1} ds. && (79) \end{aligned}$$

8.4 Computation of the asymptotic bias and variance

We follow the idea in 1-dimension in pp. 155-156 of Mykland and Zhang (2012), and define an auxiliary martingale

$$\tilde{M}_t^n = M_t^n - \int_0^t k_s^{(1)} dX_s^{(1)} - \int_0^t k_s^{1,\perp} dX_s^{1,\perp},$$

where $X_t^{1,\perp}$ is defined in (39). Using (78), we deduce

$$\begin{aligned} \langle \tilde{M}^n, X^{(1)} \rangle_t &= \langle M^n, X^{(1)} \rangle_t - \int_0^t k_s^{(1)} d\langle X^{(1)} \rangle_s \\ &\xrightarrow{\mathbb{P}} \int_0^t \phi_s^{AC1} \left(\phi_s^\tau\right)^{-1} ds - \int_0^t k_s^{(1)} \left(\sigma_s^{(1)}\right)^2 ds. \end{aligned}$$

Hence, we choose

$$k_s^{(1)} = \left(\sigma_s^{(1)}\right)^{-2} \phi_s^{AC1} \left(\phi_s^\tau\right)^{-1}.$$

By the same techniques that we used to compute (78), we have that

$$\langle M^n, \int_0^\cdot \rho_s^{1,2} \sigma_s^{(2)} dB_s^{(1)} \rangle_t \to \int_0^t \left(\sigma_s^{(1)}\right)^{-1} \sigma_s^{(2)} \rho_s^{1,2} \phi_s^{AC1} \left(\phi_s^\tau\right)^{-1} ds. \tag{80}$$

Using (79) and (80) we compute

$$\begin{aligned}
\langle \tilde{M}^n, X^{1,\perp}\rangle_t &= \langle M^n, X^{1,\perp}\rangle_t - \int_0^t k_s^{1,\perp} d\langle X^{1,\perp}\rangle_s \\
&= \langle M^n, X^{(2)} - \int_0^{\cdot} \rho_s \sigma_s^{(2)} dB_s^{(1)}\rangle_t - \int_0^t k_s^{1,\perp} d\langle X^{1,\perp}\rangle_s \\
&= \langle M^n, X^{(2)}\rangle - \langle M^n, \int_0^{\cdot} \rho_s \sigma_s^{(2)} dB_s^{(1)}\rangle_t - \int_0^t k_s^{1,\perp} d\langle X^{1,\perp}\rangle_s \\
&\xrightarrow{\mathbb{P}} \int_0^t \left(\phi_s^{AC2} - \left(\sigma_s^{(1)}\right)^{-1} \sigma_s^{(2)} \rho_s^{1,2} \phi_s^{AC1}\right) \left(\phi_s^{\tau}\right)^{-1} ds \\
&\quad - \int_0^t k_s^{1,\perp} \left(1 - \left(\rho_s^{1,2}\right)^2\right) \left(\sigma_s^{(2)}\right)^2 ds.
\end{aligned}$$

Hence, we choose

$$k_s^{1,\perp} = \left(1 - \left(\rho_s^{1,2}\right)^2\right)^{-1} \left(\left(\sigma_s^{(2)}\right)^{-2} \phi_s^{AC2} - \left(\sigma_s^{(1)}\sigma_s^{(2)}\right)^{-1} \rho_s^{1,2} \phi_s^{AC1}\right) \left(\phi_s^{\tau}\right)^{-1}.$$

By $(A4)$, there exists $S > 0$ such that the S Brownian motions $\{D^{(1)}, ..., D^{(S)}\}$ generate the filtration $(\mathcal{F}_t)_{t \geq 0}$. To show that $\langle \tilde{M}^n, D^{(s)}\rangle_t$ tends to 0 in probability, we decompose $D^{(s)} = D^{s,1} + D^{s,2}$ where $D^{s,1}$ belongs to the space spanned by $\{X^{(1)}, X^{(2)}\}$, $D^{s,2}$ is orthogonal to this space. By what precedes, we have clearly $\langle \tilde{M}^n, D^{s,1}\rangle_t$ tends to 0 in probability. Also, $D^{s,2}$ is a martingale that is, conditionally on the observations times of both processes, independent of $\tilde{M}^n$. Thus we also deduce that $\langle \tilde{M}^n, D^{s,2}\rangle_t$ converges to 0 in probability.

We can now compute

$$\begin{aligned}
\langle \tilde{M}^n\rangle_t &= \langle M^n - \int_0^{\cdot} k_s^{(1)} dX_s^{(1)} - \int_0^{\cdot} k_s^{1,\perp} dX_s^{1,\perp}\rangle_t \\
&= \langle M^n\rangle_t + \int_0^t \left(\sigma_s^{(1)}\right)^2 \left(k_s^{(1)}\right)^2 ds + \int_0^t \left(\sigma_s^{(2)}\right)^2 \left(1 - \left(\rho_s^{1,2}\right)^2\right) \left(k_s^{1,\perp}\right)^2 ds \\
&- 2\int_0^t k_s^{(1)} d\langle X^{(1)}, M^n\rangle_s - 2\int_0^t k_s^{1,\perp} d\langle X^{1,\perp}, M^n\rangle_s \\
&\xrightarrow{\mathbb{P}} \int_0^t \left(\phi_s^{AV} + 2\left(k_s^{(1)} \left(\sigma_s^{(1)}\right)^{-1} \sigma_s^{(2)} \rho_s^{1,2} \phi_s^{AC1} - \left(k_s^1 + k_s^{1,\perp}\right) \phi_s^{AC2}\right)\right) \left(\phi_s^{\tau}\right)^{-1} \\
&+ \left(\sigma_s^{(1)}\right)^2 \left(k_s^{(1)}\right)^2 + \left(\sigma_s^{(2)}\right)^2 \left(1 - \left(\rho_s^{1,2}\right)^2\right) \left(k_s^{1,\perp}\right)^2 ds.
\end{aligned}$$

By letting

$$\begin{aligned} AV_s &= \left(\phi_s^{AV} + 2\left(k_s^{(1)}\left(\sigma_s^{(1)}\right)^{-1}\sigma_s^{(2)}\rho_s^{1,2}\phi_s^{AC1} - \left(k_s^{(1)} + k_s^{1,\perp}\right)\phi_s^{AC2}\right)\right)\left(\phi_s^{\tau}\right)^{-1} \\ &\quad + \left(\sigma_s^{(1)}\right)^2\left(k_s^{(1)}\right)^2 + \left(\sigma_s^{(2)}\right)^2\left(1 - \left(\rho_s^{1,2}\right)^2\right)\left(k_s^{1,\perp}\right)^2, \end{aligned}$$

we deduce using Theorem 2.28 in Mykland and Zhang (2012) that stably in law as $\alpha_n \to 0$,

$$\alpha_n^{-1}\left(\widehat{RCV}_{t,n} - RCV_t\right) \to \int_0^t k_s^{(1)} dX_s^{(1)} + \int_0^t k_s^{1,\perp} dX_s^{1,\perp} + \int_0^t \left(AV_s\right)^{1/2} d\tilde{W}_s.$$

We have just shown Theorem 1. Now, we express the asymptotic bias $AB_t = \int_0^t k_s^{(1)} dX_s^{(1)} + \int_0^t k_s^{1,\perp} dX_s^{1,\perp}$ differently as

$$\begin{aligned} AB_t &= \int_0^t k_s^{(1)} dX_s^{(1)} + \int_0^t k_s^{1,\perp}(1 - \left(\rho_s^{1,2}\right)^2)^{1/2}\sigma_s^{(2)} dB_s^{1,\perp} \\ &= \int_0^t k_s^{(1)} dX_s^{(1)} - \int_0^t k_s^{1,\perp}\rho_s^{1,2}\sigma_s^{(2)} dB_s^{(1)} + \int_0^t k_s^{1,\perp}\rho_s^{1,2}\sigma_s^{(2)} dB_s^{(1)} \\ &\quad + \int_0^t k_s^{1,\perp}\left(1 - \left(\rho_s^{1,2}\right)^2\right)^{1/2}\sigma_s^{(2)} dW_s^{1,\perp} \\ &= \int_0^t \left(k_s^{(1)} - k_s^{1,\perp}\rho_s^{1,2}\sigma_s^{(2)}\left(\sigma_s^{(1)}\right)^{-1}\right) dX_s^{(1)} + \int_0^t k_s^{1,\perp} dX_s^{(2)}. \end{aligned}$$

We thus deduce the expression of $AB_s^{(1)}$ and $AB_s^{(2)}$.

The proof of Corollary 4 follows in the same way as the proof of Theorem 1. We hold constant the asymptotic variance and the asymptotic bias on blocks of size h_n. Moreover, we can see that $\widehat{AB}_{i,\alpha}^{(1)}$, $\widehat{AB}_{i,\alpha}^{(2)}$ and $\widehat{AV}_{i,\alpha}$ are uniformly consistent estimators under the constant model.

8.5 Discussion on the adaptation of Theorem 1 proofs for more general models

We discuss in this section how to adapt the proofs of Theorem 1 when considering Example 3 up to Example 6. In that case, the HBT can be defined for each $k = 1, 2$ as $\tau_{0,n} := 0$ and recursively as

$$\tau_{i,n}^{(k)} := \inf\left\{t > \tau_{i-1,n}^{(k)} : \Delta X^{(t,k)}_{[\tau_{i-1,n}^{(k)}, t]} \notin \left[\alpha_n d_{t,n}^{(k)}\big(t - \tau_{i-1,n}^{(k)}\big), \alpha_n u_{t,n}^{(k)}\big(t - \tau_{i-1,n}^{(k)}\big)\right]\right\} \qquad (81)$$

for any positive integer i. In (81), the grid $g_{t,n}^{(k)} := (d_{t,n}^{(k)}, u_{t,n}^{(k)})$ depends on n, thus the term $g_t^{(k)}$ in the asymptotic variance obtained in Theorem 1 will have a different interpretation. Indeed, $g_t^{(k)}$ will be seen as a (possibly multidimensional) continuous time-varying parameter which generates (81) instead of the scaled grid function itself. In particular, the approximations will not be carried with holding $g_{t,n}$ constant on each block, but rather with holding g_t constant on each block. Also, for any fixed $t \in [0,1]$, $g_t^{(k)}$ will not be a function on $\mathbb{R}^+$, but a simple vector. The reader can refer to Potiron (2016) for the notion of time-varying parameter. Note that Assumption (A3) is only used in Lemma 11 and Lemma 14. Thus, Lemma 11 and Lemma 14 are the only parts in the proof which need to be adapted.

8.5.1 Example 3 (hitting constant boundaries of the jump size)

For each asset $k = 1, 2$ we define the jump sizes as $L_{i,n}^{(k)}$. We assume that $L_{i,n}^{(1)}$ and $L_{i,n}^{(2)}$ are independent of each other. We have that $g_{t,n}^{(k)}(s) := (-L_{i-1,n}^{(k)}, L_{i-1,n}^{(k)})$ for $t \in (\tau_{i-1,n}^{(k)}, \tau_{i,n}^{(k)}]$. We also have a non-time varying parameter $g_t := 1$.

As the jump size $L_{i,n}^{(k)}$ are IID and independent of the other quantities, we can consider the same $L_{i,n}^{(k)}$ when making local approximations. Note that in Lemma 11, the proof is made recursively for each observation time of the block. Thus a "jump" of $g_{t,n}$ is not a problem when it happens exactly at observation times, as long as the same jump is also made in the approximation block. Since $L_{i,n}^{(k)}$ is assumed to be bounded, it is straightforward to adapt the proof of Lemma 11.

We discuss now how to adapt the proof of Lemma 14. To do that, we consider the Markov chain $\tilde{Z}_i := \big(\Delta\tilde{X}^{(2)}_{[\tilde{\tau}_i^{1C,-}, \tilde{\tau}_i^{1C}]}, \tilde{\tau}_i^{1C} - \tilde{\tau}_i^{1C,-}, L_{i'}^{(1)}, L_{j'}^{(2)}\big)$, where i' is such that $\tilde{\tau}_{i'}^{(1)} = \tilde{\tau}_i^{1C}$, j' is such that $\tilde{\tau}_{j'}^{(2)} = \tilde{\tau}_i^{1C,-}$, $L_i^{(1)}$ and $L_i^{(2)}$ are IID sequences independent of each other which follows respectively the distribution of $L_{i,1}^{(1)}$ and $L_{i,1}^{(2)}$. Then, everything follows the same way as in the proof of Lemma 14.

8.5.2 Example 4 (model with uncertainty zones)

This model is very similar to Example 3, except that the sequence $L_{i,n}^{(k)}$ is obtained as a function of $\chi_{\tau_{i,n}}^{(k)}$, where $\chi_t^{(k)}$ corresponds to the continuous time-varying parameter χ_t

of the kth asset introduced in p. 5 of Robert and Rosenbaum (2012). We thus consider $g_t^{(k)} := \chi_t^{(k)}$. The proof of Lemma 11 can be extended using the convenient construction of $L_{i,n}^{(k)}$ provided in p. 11 of Robert and Rosenbaum (2012). We extend this construction in two-dimension assuming that $(W_t')^{(1)}$ and $(W_t')^{(2)}$ are independent. As Example 4 is slightly more involved than Example 3, the Markov chain $\tilde{Z}_i$ needs to include also the type of previous price change (increment or decrement) for each asset. We thus consider $\tilde{Z}_i := \big(\Delta \tilde{X}^{(2)}_{[\tilde{\tau}_i^{1C,-}, \tilde{\tau}_i^{1C}]}, \tilde{\tau}_i^{1C} - \tilde{\tau}_i^{1C,-},\ L_{i'}^{(1)},\ L_{j'}^{(2)}, \mathrm{sign}(\Delta \tilde{X}^{(1)}_{\tilde{\tau}^{(1)}_{i'}}), \mathrm{sign}(\Delta \tilde{X}^{(2)}_{\tilde{\tau}^{(2)}_{j'}})\big)$, and can follow the same line of reasoning as in Lemma 14.

8.5.3 Example 5 (times generated by hitting an irregular grid model)

In this case, the parameter $g_t^{(k)} := 1$ is non time-varying. Lemma 11 can be adapted easily. To show Lemma 14, a further condition is needed on $q_j^{(k)} := p_j^{(k)} - p_{j-1}^{(k)}$. We assume that there exists a positive number $Q^{(k)}$ such that for any non-negative number j and any $l \in \{0, \cdots, Q^{(k)} - 1\}$ we have $q^{(k)}_{jQ^{(k)}+l} = q_l^{(k)}$. We also define the Markov chain $\tilde{Z}_i := \big(\Delta \tilde{X}^{(2)}_{[\tilde{\tau}_i^{1C,-}, \tilde{\tau}_i^{1C}]}, \tilde{\tau}_i^{1C} - \tilde{\tau}_i^{1C,-}, l^{(1)}, l^{(2)}\big)$, where $l^{(1)}$ is the index such that there exists a non-negative number m with $p^{(1)}_{mQ^{(1)}+l^{(1)}} = \tilde{X}^{(1)}_{\tilde{\tau}_i^{1C}}$, and $l^{(2)}$ is the index such that there exists a non-negative number m with $p^{(2)}_{mQ^{(2)}+l^{(2)}} = \tilde{X}^{(2)}_{\tilde{\tau}_i^{1C,-}}$. Under this assumption, we can show Lemma 14.

8.5.4 Example 6 (structural autoregressive conditional duration model)

We assume that the mixing variables $\tilde{d}^{(k)}_{\tau_{i,n}}$ and $\tilde{c}^{(k)}_{\tau_{i,n}}$ are interpolated by time-varying continuous stochastic parameters $(\tilde{d}_t^{(k)}, \tilde{c}_t^{(k)})$. We have that $g_t^{(k)} := (\tilde{d}_t^{(k)}, \tilde{c}_t^{(k)})$. The central limit theorem in Example 6 can be obtained as a straightforward corollary of Theorem 1. If we define for any $s \geq 0$ the grid functions $g_t^{(k)}(s) := (\tilde{d}_t^{(k)}, \tilde{c}_t^{(k)})$, the only difference between the HBT model (5) and the structural ACD model (6) is that we hold the grid between two observations in the latter model. In view of this specific assumption which implicates that the quantities of approximation are closer to the approximated quantities than under the HBT model, the proof of Lemma 11 simplifies. The proof of Lemma 14 remains unchanged as it deals only with quantities of approximation.

8.6 Jump case: proof of Remark 6

We update in this section the proof in the jump case model (14). The idea is to exclude all the blocks where we observe a jump. Such blocks will be finitely counted, and we will have at most one jump (either for $Y_t^{(1)}$ or for $Y_t^{(2)}$ but not for both prices at the same time) in each block. This is the main difference with the one-dimensional case.

We introduce the notation

$$A_n^{(no)} := \left\{ i \geq 1 \text{ s.t. } \tau_{i-1,n}^h \leq t \text{ and there is no jumps on } [\tau_{i-1,n}^h, \tau_{i,n}^h] \right\}.$$

The proof of Lemma 5 can be adapted because of the finiteness of jumps. The proof of Lemma 6 remains unchanged. Lemma 7 and Lemma 8 remains true in view of the finiteness of jumps. Lemma 9 and Lemma 10 don't need any change. We modify Lemma 11 as follows. Let $l \geq 1$, we have that

$$\sup_{i \in A_n^{(no)}\ ,\ 2 \leq j \leq h_n} \mathbb{E}\left[\left| \Delta\tau_{i,j,n}^{1C} - \Delta\tilde{\tau}_{i,j,n}^{1C} \right|^l \right] = o_p\left(\alpha_n^{2l}\right)$$

and

$$\sup_{i \in A_n^{(no)}\ ,\ 2 \leq j \leq h_n} \mathbb{E}\left[\left| \Delta\tau_{i,j,n}^{1C,-,+} - \Delta\tilde{\tau}_{i,j,n}^{1C,-,+} \right|^l \right] = o_p\left(\alpha_n^{2l}\right)$$

The proof remains unchanged in view of the independence assumption between jumps and the other quantities. Lemma 12 stays true with no further change. We introduce the new following lemma to be inserted between Lemma 12 and Lemma 13 in the proofs.

Lemma 16. *We have*

$$\alpha_n^{-2} \sum_{i \in A_n} \mathbb{E}_{\tau_{i-1,n}^h}\left[\sum_{u=2}^{h_n} \left(N_{(i-1)h_n+u}\right)^2 + 2N_{(i-1)h_n+u}N_{(i-1)h_n+u+1} \right]$$

$$= \alpha_n^{-2} \sum_{i \in A_n^{(no)}} \mathbb{E}_{\tau_{i-1,n}^h}\left[\sum_{u=2}^{h_n} \left(N_{(i-1)h_n+u}\right)^2 + 2N_{(i-1)h_n+u}N_{(i-1)h_n+u+1} \right] + o_p(1)$$

Proof. This is a simple consequence to the fact that we have at most one jump in $\Delta X_{\tau_{i,n}^{1C}}^{(1)}$ or $\Delta X_{\tau_{i,n}^{1C,-,+}}^{(2)}$ asymptotically, together with the finiteness of jumps. □

Starting from Lemma 13 up to the end of the proof of Theorem 1, in view of Lemma 16, we can use "$i \in A_n^{(no)}$" in lieu of "$i \in A_n$". We have thus proved that Theorem 1 is robust to jumps.

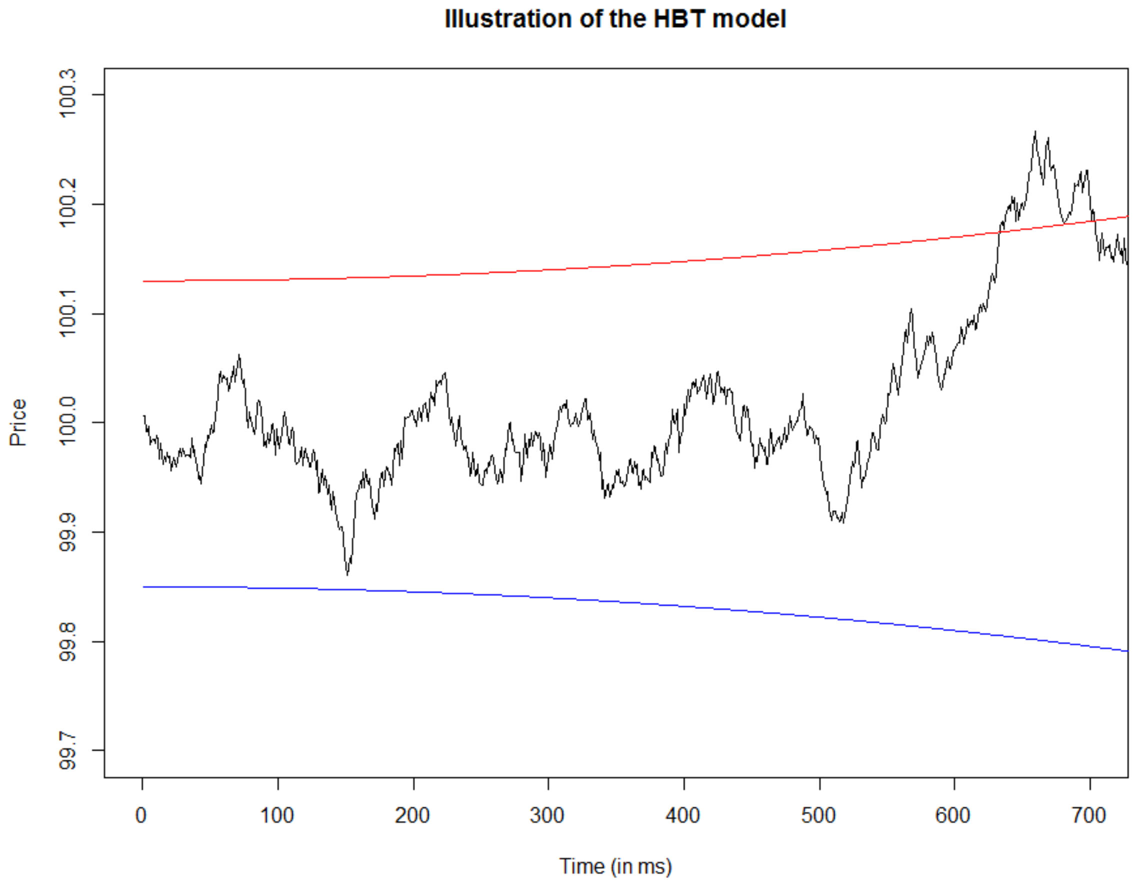

Figure 1: This is an illustration of the HBT model when starting at time $\tau_0 = 0$ and with $X_0 = 100$. The black stochastic process represents X_t, the red line stands for $100 + u_t(t)$ and the blue line for $100 + d_t(t)$. Furthermore, we assume that $X_t^{(t)} = X_t$. The second observation τ_1 is obtained when X_t crosses the red line for the first time.

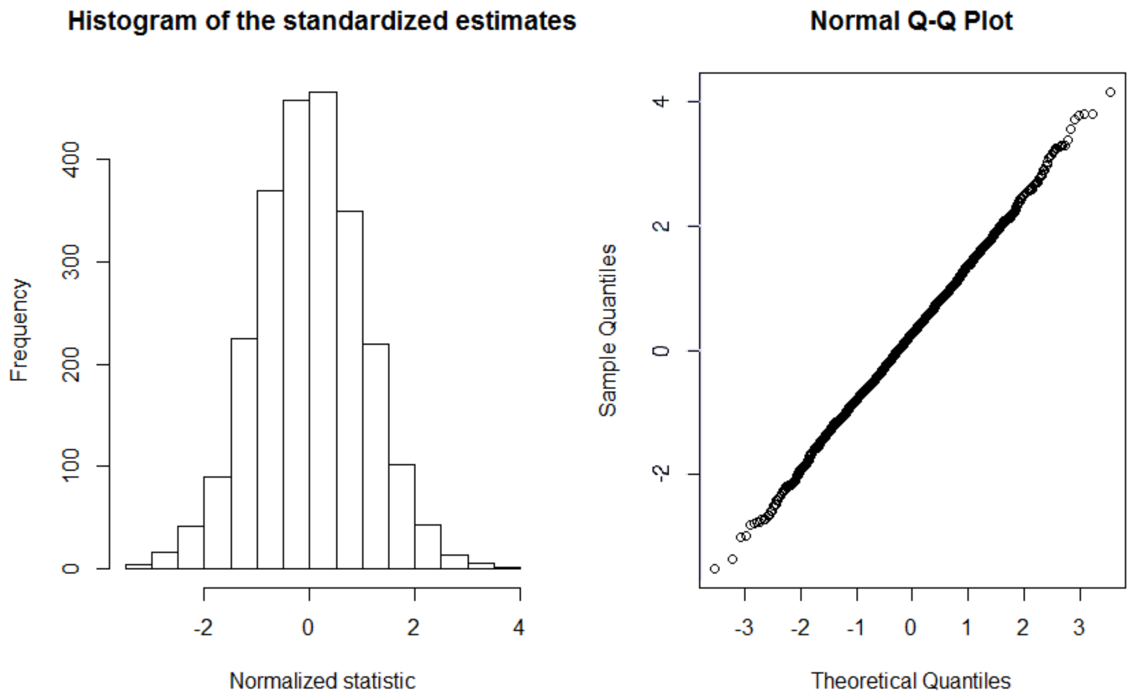

Figure 2: Histogram and Normal QQ-plot of the standardized estimates (50) in setting 1 on a 10-year period of observations.
